Executive Steering Committee Charter

Executive Steering Committee Charter

Delaware Bay Area Committee Charter

1. Purpose and Mission

1.1. The Delaware Bay Area Committee, created under the Oil Pollution Act of 1990, is a component of the National Response System, as established under the National Oil and Hazardous Substances Contingency Plan (NCP). The Area Committee complements the National Preparedness System as defined by the Department of Homeland Security (DHS), by facilitating preparedness efforts of the "whole community" to promote and strengthen the National Preparedness mission areas of Prevention, Protection, Mitigation, Response, and Recovery. The Area Committee prepares an Area Contingency Plan (ACP) for their area, under the direction of the Federal On-Scene Coordinator (FOSC) and in conjunction with the Regional Response Teams (RRT), National Strike Force, State Emergency Response Commissions (SERCs), Local Emergency Planning Committees (LEPCs), the District Response Advisory Team and Preparedness Staff, Scientific Support Coordinator, and other stakeholders. The Area Committee also promotes affirmative conservation of threatened and endangered species and historical/cultural resources, in accordance with applicable law. The Area Committee's Executive Steering Committee (ESC) performs strategic oversight and provides direction for fulfillment of Area Committee missions and initiatives. The Executive Steering Committee (ESC) will focus their efforts on strengthening public-private preparation and response partnerships and pre-planning; engaging stakeholders; maintaining and improving the ACP, including Geographic Response Strategies; and setting strategic priorities and work plans for training, exercises, and/or other preparedness initiatives.

2. Composition

2.1. Per the Coast Guard Marine Environmental Response Manual, COMDTINST M16000.14(series), broad Area Committee representation provides for effective spill response planning and preparedness. Appendix A of the Marine Environmental Response Manual contains a list of agencies for potential inclusion on the Area Committee.

2.2. The ESC will function as a representational team of government, non-government organizations (NGO), and members of the private sector. This team has a shared role in preparedness and response activities within Coastal Zone, as defined by the 1997 Coast Guard/EPA Memorandum of Understanding and ACP, within Sector Delaware Bay's Captain of the Port (COTP) area of responsibility, as defined by Title 33 of the Code of Federal Regulations (CFR) part 3.25.

2.3. The Commander, Coast Guard Sector Delaware Bay, serves as the FOSC in the Coastal Zone, and is the Chairman of the ESC and the Area Committee. The FOSC, in consultation with the state agency Area Committee representatives from New Jersey,

Delaware, and Pennsylvania, designates a State co-chairman to serve on an annual basis from January 1 through December 31. The charter members of the ESC represent a broad spectrum of interests, expertise, and jurisdictions from the COTP zone to provide for effective contingency response planning and preparedness. The default composition of the ESC should include the following:

ESC Appointed Permanent Members	ESC At-Large Representatives
• USCG, Federal On-Scene Coordinator	• Oil Spill Response Organization (OSRO) Rep
• NJ State Representative	• Wildlife Response/Rehabilitation NGO
• DE State Representative	• Estuary/Water Environmental Quality NGO
• PA State Representative	• Industry Technical Specialist(s): Vessel
• NOAA	• Industry Technical Specialist: Facility
• DOI / USFWS Representative(s)	• Industry Technical Specialist: Pipeline
• US Army Corp of Engineers	• Industry Technical Specialist: Rail
• EPA Regions 2 and 3 (advisors)	• Local Emergency Preparedness Committee (LEPC) Rep
	• Sub Committee Chair(s)

Table 1

2.4. In accordance with Coast Guard Marine Environmental Response Manual, COMDTINST M16000.14(series), the FOSC will designate in writing all Appointed Permanent Executive Committee members. These members will serve indefinitely until a replacement is appointed. In coordination with ESC members, the FOSC will invite At-Large Representatives to participate on the ESC for a term of three years. The ESC may solicit a particular individual to fill an At-Large position based on a specific and desirable skill set or experience, or solicit applicants from the General Members of the Area Committee. If a pool of potential candidates for a particular position is desired, a solicitation will be advertised electronically to the Area Committee general membership, and verbally at an Area Committee general members meeting. Applicants will be asked to provide a resume and/or letter of interest to the ESC, via the Executive Secretary, by a set deadline. The ESC will decide on the method for filling a particular position (i.e. targeted individual outreach or solicitation for candidates) by majority vote, and in accordance with paragraphs 5 and 6 of this Charter. There is no limit to the amount of sequential terms that At-Large Representatives may serve. However, At-Large positions should be re-solicited from within the Area Committee upon vacancy or end of term so that the ESC may consider best qualified individuals to serve in respective roles.

3. Roles and Responsibilities

3.1. FOSC: The Commander, Coast Guard Sector Delaware Bay is the FOSC, and serves as the Chair of the ESC and Area Committee. In the absence of the Sector Commander, the Deputy Sector Commander will serve as Chair. The FOSC is ultimately responsible for ensuring the ESC and Area Committee fulfills its mission and purpose and adheres to the terms of this Charter. The FOSC or his/her designee will communicate ESC and

Area Committee business or issues, as deemed appropriate, up the Coast Guard chain of command. The FOSC will ensure continuing USCG administrative and logistical support of the ESC and Area Committee by appointing an Executive Secretary.

3.2. Executive Secretary: The Civilian Contingency Preparedness Specialist on Sector Delaware Bay's Contingency Planning Staff serves as the Area Committee and ESC Executive Secretary. The Executive Secretary is a non-voting member responsible for administrative and logistical support of the ESC and Area Committee, including but not limited to: coordinating Area Committee and ESC meetings, formatting/disseminating meeting agendas and minutes, completing the Area Committee's Annual Report, managing appointment letters, and other tasks assigned by the FOSC and/or Co-Chair.

3.3. ESC and Area Committee Co-Chair: The Co-Chair shall be a State representative (normally from the respective states' environmental protection/response agency and/or a State On-Scene Coordinator) from New Jersey, Delaware, or Pennsylvania who serves a one-year term. The Co-Chair position will rotate between the three state representatives, turning over annually on 1 January (PA 2018, DE 2019, NJ 2020, and so on). The Co-Chair is responsible for developing or recommending meeting agenda topics, and will personally facilitate ESC meetings during their time as Co-Chair. Additionally, the Co-Chair will assist in providing a summary of Area Committee initiatives and accomplishments from the previous year to the Executive Secretary annually in January for inclusion in the Area Committee Annual Report. The Co-Chair shall ensure that the ESC and Area Committee operate in accordance with this Charter and other applicable policy/guidance. The Executive Secretary will advise and assist the Co-Chair in the performance of these duties.

3.4. ESC Members: Sector Delaware Bay ESC members (Appointed and At-Large) will represent their entity and/or stakeholder group in support of the Area Committee's mission and purpose. Appointed and At-Large members may designate an alternate to represent on their behalf during ESC meetings, should the appointed or At-Large member be unavailable. ESC members should weigh in on and/or vote upon strategic issues, projects, or initiatives, examine or research particular issues within their areas of expertise, develop recommendations for action, and assist with the development of topical areas of focus for Area Committee meetings/activities.

3.5. Enclosure (1) contains a complete list and descriptions of ESC representative positions.

3.6. General Area Committee Members: The FOSC, in consultation with ESC members, allows port stakeholders to participate in the Area Committee and its activities. These port stakeholders are referred to as general members. All general members must conform to all applicable requirements, procedures, and protocols for Area Committee activities. General members may assist the ESC and Area Committee individually or as representatives of the organizations with which they are affiliated, and may include, but are not limited to, subject matter experts whose input is necessary in the development of the ACP or other activities. General members may participate in the

activities of sub-committees and work groups. General members are representative of federal, state, tribal, territorial, and local agencies; non-government organizations, marine industry; and other port stakeholders. Representatives for each aspect of the ACP, and those charged with its regulation and/or management, are encouraged to participate.

General Area Committee members are responsible for, but not limited to:

- Recommending ACP enhancement strategies that are realistic and commensurate with expected risks including plans, practices, exercises and procedures to safely respond to, mitigate the effects of, and recover from environmental incidents;
- Assisting the ESC and Area Committee in reviewing and updating the ACP;
- Participating in exercising of the ACP;
- Promoting inter-agency collaboration and preparedness; and
- Keeping abreast of, and sharing, "best practices" that may be of value to the Area Committee.

3.7. Sub-committees and Workgroups: Additional standing sub-committees and/or workgroups may be established upon approval of the ESC. The ESC will determine membership and/or target audience of such sub-committees or workgroups, unless otherwise established via applicable Charter for the sub-committee or workgroup. ESC members may be asked to contribute personnel, resources, or leadership to support sub-committee or workgroup activities. As of the writing of this Charter, the Marine Firefighting Sub-Committee is a standing sub-committee of the Area Committee, and is established and administered in accordance with its Charter (enclosure 2).

4. Meetings

4.1 There are three types of meetings: ESC meetings, Area Committee meetings, and Sub-Committee/Workgroup meetings. ESC meetings shall occur at least twice annually, but may be held quarterly at the discretion of the FOSC and ESC. In accordance with Coast Guard policy, Area Committee General Member Meetings shall occur at least twice annually. However, Delaware Bay Area Committee meetings and Executive Steering Committee meetings generally occur quarterly. Sub-committee and/or Working Group meetings are held as needed.

4.2 Area Committee meetings are held to share information relevant to the mission and purpose of the Area Committee, enable members to introduce topics, receive updates on projects, and conduct such business as deemed necessary and appropriate.

4.3 The Executive Secretary is responsible for communicating the dates of meetings as far in advance as practicable to the Area Committee membership in order to encourage maximum attendance. The Executive Secretary will disseminate agendas for ESC and Area Committee General Members Meetings no later than five working days prior to the meeting.

4.4 ESC meetings are held to discuss and provide strategic direction, make recommendations, and to review and vote on actions, projects, and/or tasks raised by the general membership or other ESC members. Additionally, ESC meetings are used to monitor the progress of the various projects and tasking, provide such guidance as may be necessary to effectively and efficiently carry out those projects and tasking, and carry out the functions of the ESC. Special Meetings may be conducted to address topics of a unique or time critical nature with as much notice given to ESC member as practicable. Special meetings may be conducted remotely if appropriate (i.e. conference call).

4.5 Meeting Rules and Administration: Robert's Rules of Order will guide the manner in which the FOSC and Co-Chair conduct ESC and Area Committee meetings. At a minimum, minutes shall include the date of the meeting, the list of attendees, a synopsis of items discussed and any recommendations, future action items, or accomplishments. The Executive Secretary will draft minutes from ESC and Area Committee meetings within 15 business days after the conclusion of the meeting, and disseminate to the ESC when completed.

4.6 All ESC meetings are closed to the general membership and public unless authorized by the FOSC. Requests by the general membership and public to attend ESC meetings may be submitted through the Executive Secretary. Members of the general public wishing to attend an Area Committee meeting will coordinate through the Executive Secretary. All guests shall be directed/introduced to the Executive Secretary for check-in prior to the start of the meeting.

5. Voting

5.1. Area Committee Meetings. No formal voting is conducted at a general membership meeting. This meeting is for information sharing only.

5.2. ESC Meetings. At the discretion of the FOSC, Co-Chair, or ESC membership, motions will be introduced and voted upon. Motions receiving a majority vote of a duly constituted quorum of the ESC membership shall be adopted, and recorded in the meeting minutes. Appointed and At-Large ESC members will receive one vote (note: Representatives of EPA Regions 2 and 3 are advisors and do not vote). Designated alternates may only vote when the ESC member they represent is absent. A duly constituted quorum is established when a simple majority of the ESC membership is represented in person and/or telephonically.

5.3. Voting may be conducted via teleconference or electronically on a case by case basis.

6. Compensation

6.1 ESC and Area Committee members do not receive reimbursement of any kind from the Coast Guard.

7. **Amendments**

7.1. Motions to amend this charter may be introduced by ESC members for discussion and vote. Amendment motions will be handled in accordance with paragraph 5.

8. **Records**

8.1. The FOSC will ensure that Area Committee business is documented in accordance with applicable policy, and this Charter. On behalf of the FOSC, the Executive Secretary maintains records of the ESC and Area Committee. Record keeping includes, but is not limited to, the following:

- ESC member appointment letters;
- ESC and Area Committee meeting agendas, attendance lists, and minutes;
- Documents recording key decisions and actions approved by the ESC and Area Committee;
- Subcommittee reports;
- Annual Area Committee Reports.
- Current edition of the ACP, including digital versions.

8.2 All records will be kept in the Coast Guards electronic data system, maintained by the Executive Secretary. Meeting agendas and minutes will also be posted to Homeport.

8.3. All ESC and Area Committee General Member meeting dates, agendas, meeting minutes, and the Area Committee Annual Report will be posted on the Sector Delaware Bay Homeport page.

#

Date: 8 JAN 2019

Scott Anderson, Captain
USCG Federal On Scene Coordinator

Representative	Notes	Voting Status	Appointed or At Large	Type
USCG, SDB - Federal On Scene Coordinator	The Commander, Coast Guard Sector Delaware Bay is the FOSC, and is the Chair of the ESC and Area Committee. In the absence of, or by direction of the Sector Commander, the Deputy Sector Commander will serve as an Alternate FOSC.	Yes	N/A	Indefinite
Executive Secretary	The Executive Secretary is a Coast Guard member appointed by the FOSC and is a non-voting member of the ESC. The Executive Secretary will be responsible for administrative and logistical support of the ESC and Area Committee, including coordinating meetings, ensuring adequate record keeping, and other tasks assigned by the FOSC or Co-Chair.	No	N/A	Indefinite
PA State Representative	This representative is appointed by the FOSC to serve on the Area Committee and Executive Steering Committee. This is typically a State On Scene Coordinator (SOSC), or representative of the State's environmental response/protection agency. This member will represent the interests and concerns of his or her State. Duties include but are not limited to reviewing and updating the ACP, helping the Executive Steering Committee identify and work on strategic issues, assisting with exercise design and execution. Other state representatives may attend meetings with, or in place of, the primary state representative. Regardless of the number of representatives attending a meeting, PA gets a single vote.	Yes	Appointed	Indefinite
DE State Representative	This representative is appointed by the FOSC to serve on the Area Committee and Executive Steering Committee. This is typically a State On Scene Coordinator (SOSC), or representative of the State's environmental response/protection agency. This member will represent the interests and concerns of his or her State. Duties include but are not limited to reviewing and updating the ACP, helping the Executive Steering Committee identify and work on strategic issues, assisting with exercise design and execution. Other state representatives may attend meetings with or in place of the primary state representative. Regardless of the number of representatives attending a meeting, DE gets a single vote.	Yes	Appointed	Indefinite
NJ State Representative	This representative is appointed by the FOSC to serve on the Area Committee and Executive Steering Committee. This is typically a State On Scene Coordinator (SOSC), or representative of the State's environmental response/protection agency. This member will represent the interests and concerns of his or her State. Duties include but are not limited to reviewing and updating the ACP, helping the Executive Steering Committee identify and work on strategic issues, assisting with exercise design and execution. Other state representatives may attend meetings with or in place of the primary state representative. Regardless of the number of representatives attending a meeting, NJ gets a single vote.	Yes	Appointed	Indefinite
US Army Corps or Engineers	This is a seat that is filled by a representative of the Army Corps of Engineers as the USACE has equipment and or responsibilities to maintain the federal channel. If the primary Representative is not available, another employee of USACE attends meetings. Regardless of the number of representatives attending a meeting, USACE gets a single vote.	Yes	Appointed	Indefinite

Representative	Notes	Voting Status	Appointed or At Large	Type
Dept. of the Interior	This is a seat filled by a representative of the Department of The Interior as the DOI has responsibilities to protect and care for flora and fauna. The DOI representative has connections to USFWS field experts and Wildlife Refuge Managers in the area. Duties include, but are not limited to, reviewing and updating the ACP, helping design and participate in exercises, and participate in spill responses. Regardless of the number of representatives attending a meeting, DOI gets a single vote.	Yes	Appointed	Indefinite
USFWS	This is a permanent seat filled by a USFWS Representative. The position is a technical expert. Duties are similar to other positions. The representative is to help maintain the ACP, help design exercises, and advise the FOSC of wildlife concerns/considerations during pre-planning and during spill responses. This is a non-voting seat if DOI Representative is attendance at the ESC meeting. There is not an alternate for this position.	Yes	Appointed	Indefinite
NOAA	This is a permanent seat. The assigned Scientific Support Coordinator for the Sector fills the NOAA representative seat. The NOAA representative helps prepare responders for a spill response and offer technical assistance to the USCG during a spill. There is no alternate for this seat. Regardless of the number of representatives attending a meeting, NOAA gets a single vote.	Yes	Appointed	Indefinite
EPA II	This is a permanent advisory seat. As such, the agency does not vote on Area Committee business. The EPA representative from Region II advises the ESC and AC on environmental issues affecting the Coastal Zone. Duties include, but are not limited to, reviewing and updating the ACP,and helping design and participate in exercises.	No	N/A (Observer)	Indefinite
EPA III	This is a permanent advisory seat. As such, the agency does not vote on Area Committee business. The EPA representative from Region III advises the ESC and AC on environmental issues affecting the Coastal Zone. Duties include, but are not limited to, reviewing and updating the ACP,and helping design and participate in exercises.	No	N/A (Observer)	Indefinite
Oil Spill Removal Organizations	This seat represents the interests, capabilities, and concerns of the Oil Spill Removal Organizations (OSRO). The representative helps keep the ESC/AC informed of recent OSRO activities and capabilities. Because Delaware Bay and River Co-operative either hires other OSROs or works closely with other Co-ops, it has been a practice that the President of the DBRC would fill this seat. When the President of DBRC is not available, another employee of DBRC fills in for the President.	Yes	At Large	Term
Wildlife Response/Rehabilitation NGO	The Wildlife Resposne/Rehabilitation NGO position will represent the interests, capabilities, and concerns of wildlife response and/or rehabilitation. This individual should be from an established entity with wildlife research, response, and rehabilitation in their core missions. The organization should also have a program and/or expertise for the use of volunteers, with a well developed volunteer training program. The designated representative may send an altenate with similar qualifications.	Yes	At Large	Term

Representative	Notes	Voting Status	Appointed or At Large	Type
Estuary/Water Environmental Quality NGO	The Estuary/Water Environmental Quality NGO position will represent a research, scientific, and/or special interest in the maritime environment. The desired area of expertise for this position may be determined by the ESC based upon risk areas and/or areas of focus within the FOSC zone (i.e. Bay and River estuary, coastal, etc). This representative may help review and update portions of the ACP and help design and participate in exercises.	Yes	At Large	Term
Industry Technical Specialist: Vessel	The Industry Technical Specialist for Vessels will provide subject matter expertise for vessels and/or cargos (particularly oil/hazmat) operating within the port. This individual should have knowledge/experience with vessel response plans, and higher risk vessels/cargos operating in the port. This representative should also be well-versed in current operations, trends, and future outlook for port/vessel/cargo industry operations. This representative may help review and update portions of the ACP and help design and participate in exercises.	Yes	At Large	Term
Industry Technical Specialist: Facility	The Industry Technical Specialist for Facilities will represent regulated facility Operations & Emergency Response. Preferred background/experience includes facility emergency response planning/operations, and safety/environmental health, with an emphasis on higher risk/higher consequence facilities in the port (i.e. oil, refining, and/or chemical handling facilities, etc). This representative may help review and update portions of the ACP and help design and participate in exercises.	Yes	At Large	Term
Industry Technical Specialist: Pipeline	The Industry Technical Specialist for Pipelines will represent Pipeline operations, technical expertise, industry points of contact, and emergency response planning for pipelines within the FOSC zone. The representative could be a permanent or ad-hoc at-large seat for ESC business, at the ESC's discretion. This representative may help review and update portions of the ACP and help design and participate in exercises.	Yes	At Large	Term
Industry Technical Specialist: Rail	The Industry Technical Specialist for Rail will represent rail industry operations, technical expertise, industry points of contact, and emergency response planning, for rail operations within the FOSC zone. The representative will be able to provide insights into rail/cargo operations/trends within the zone, particularly those operations on rails with a water nexus. The representive will also be able to help the ESC/Area Commitee periodically review/update geographic response stategies for rail crossings, and linkage to rail emergency resposne plans, as applicable. The representative could be a permanent or ad-hoc at-large seat for ESC business, at the ESC's discretion. This representative may help review and update portions of the ACP and help design and participate in exercises.	Yes	At Large	Term
Local Emergency Planning Committee Rep	This postion will be solicited/selected from one of the LEPCs having a maritime nexus within the FOSC zone. This representative could be on a rotating basis, or specifically sought/invited to participate for a term based on a targetted/desired segment of the zone to help facilitate greater interaction/involvment with local LEPC(s), sharing of information, de-confliction, and partnership/collaboration opportunities for pre-planning and exercises.	Yes	At Large	Term

Annex CC

MOUs for USCG-EPA Regions II and III Boundaries

Region 2 Boundary

DEMARCATION OF THE INLAND AND COASTAL ZONES
BETWEEN
U.S. ENVIRONMENTAL PROTECTION AGENCY – REGION 2
AND
U.S. COAST GUARD – FIRST DISTRICT
AND
U.S. COAST GUARD – FIFTH DISTRICT
AND
U.S. COAST GUARD – NINTH DISTRICT
FOR
PRE-DESIGNATION OF ON-SCENE COORDINATORS
FOR
POLLUTION RESPONSE IN REGION 2
(THE STATES OF NEW JERSEY AND NEW YORK)

1. PARTIES. The parties to this Agreement are the United States Coast Guard (USCG) and United States Environmental Protection Agency (EPA).

2. AUTHORITY. This Agreement is authorized under the National Contingency Plan, 40 CFR 300.210(b).

3. PURPOSE. The purpose of this agreement is set forth by which EPA and the USCG define the Region 2 Inland Zone (IZ)/Coastal Zone (CZ) boundaries, in order to establish responsibility for the pre-designation of On-Scene Coordinators (OSCs[1]) for pollution response pursuant to the National Oil and Hazardous Substances Contingency Plan (NCP, 30 CFR 300). This agreement provides a precise line of demarcation between the inland and coastal zones for inclusion in the federal regional contingency plan (RCP), as called for in the NCP section 300.210(b), and in the definitions for inland and coastal zones under NCP section 300.5. This MOU also establishes a formal mechanism by which OSC authority may be transferred between EPA and the USCG during an oil and/or hazardous substance pollution incident. Implicitly included in such a transfer of OSC responsibility is the responsibility for enforcement, as provided for in the USCG and EPA Memorandum of Understanding Concerning the Enforcement of Section 311 of the Clean Water Act, entered into on March 23, 1993.

4. RESPONSIBILITIES. In the area covered under this agreement, the U.S. Environmental Protection Agency (EPA) and the U.S. Coast Guard (USCG) will carry out agency and specific pollution response responsibilities under the National Contingency Plan (NCP), the National Response Plan (NRP), the Regional Contingency Plan (RCP), and the applicable Area Contingency Plans (ACP), and will assist each other to the fullest extent possible to prevent or minimize the impacts of actual or threats of discharges of oil onto navigable waters or adjoining shorelines, and actual or threats of releases of hazardous

[1] The Coast Guard uses the term Federal On-Scene Coordinator (FOSC) to prevent confusion with the On-Scene Commander in the Search-and-Rescue community. For the purposes of this document, only the NCP term On-Scene Coordinator and acronym OSC are used.

substances into the environment. The terms of this agreement will be incorporated into the applicable RCP and ACPs.

Inland Zone

The U.S. Environmental Protection Agency (EPA) provides the pre-designated On-Scene Coordinator (OSC) for pollution response in the Inland Zone. Response to discharges or releases, or a substantial threat of such a discharge of oil or release of a hazardous substance originating within the Inland Zone, including those from unknown sources, will be the responsibility of the EPA OSC.

Incidents for which the EPA does not provide the OSC are outlined in 40 CFR 300.120(c) and (d):

- releases of hazardous substances, pollutants, or contaminants, when the release is on, or the sole source of the release is from any facility or vessel under the responsibility, custody, or control of DOD or DOE

- remedial responses to facilities controlled by federal agencies other than DOD or DOE;

- all responses involving DOD owned or controlled military weapons.

The inland zone in Region 2 consists of the environment inland of the coastal zone excluding the Great Lakes and specified ports and harbors on inland rivers described in this agreement or adjacent regional and international boundary agreements, given the specific inland/coastal zone boundary precisely described later in this agreement.

Coastal Zone

The cognizant U.S. Coast Guard Captain of the Port (COTP) is the pre-designated On-Scene Coordinator (OSC) for pollution response in the Coastal Zone. Response to discharges or releases, or a substantial threat of such a discharge of an oil or release of a hazardous substances originating within the Coastal Zone, including those from unknown sources, will be the responsibility of the U.S. Coast Guard OSC.

Incidents for which the USCG does not provide the OSC are outlined in 40 CFR 300.120(c) and (d):

- releases of hazardous substances, pollutants, or contaminants, when the release is on, or the sole source of the release is from any facility or vessel under the responsibility, custody, or control of DOD or DOE

- remedial responses to facilities owned or controlled by federal agencies other than DOD or DOE; and

- All responses involving DOD owned or controlled military weapons.

The USCG hazardous substance response role is generally limited to the emergency actions in response to hazardous substance releases, as further defined in the NCP at 40 CFR 300.120(a)(1) and the Department of Transportation (DOT)/EPA Instrument of Redelegation dated May 27, 1988.

The later-described precise inland/coastal boundary line separates the inland and coastal zones, with the coastal zone consisting of the following on the seaward side of the line: United States waters subject to the tide, United States waters of the Great Lakes, specified ports and harbors on inland rivers, waters of the contiguous zone, other waters of the high seas subject to the NCP, and the land surface or land substrata, ground waters, and ambient air proximal to those waters.

Mutual Response Support and Transfer of OSC Responsibility

The proposed boundary lines do not preclude mutual assistance between the two agencies on an incident to best utilize the expertise and capabilities of each. In certain incidents, a complete transfer of OSC responsibility may be more practical than augmenting the predesignated OSC agency with the other's expertise and resources through mutual support.

A formal agency transfer of OSC may be appropriate when:

1. A hazardous substance response changes from an emergency response to a removal action;

2. One OSC or agency is better suited to coordinate the response to a specific incident. For instance, the EPA may request the Coast Guard OSC for oil discharges near the boundary that require navigable water response, or the Coast Guard may request an EPA OSC on certain hazardous materials cases;

3. A discharge or release crosses the boundary line and the scope of potential and/or actual environmental impacts in one Zone significantly exceeds the other;

4. An OSC's emergency response workload exceeds existing capabilities; or,

5. Other incident-specific situations in which EPA and USCG determine that a formal transfer of OSC responsibility is appropriate.

The opportunity to transfer responsibility can be initiated verbally, with a follow-up of written documentation of transfer for responsibility for discharges or releases. When the OSC duties are transferred, the agreement will be confirmed in writing by utilizing the attached Statement of Transfer Federal OSC Responsibility.

Incident Origin and Seepage Sites

When discharges or releases are discovered to have originated from the zone other than originally thought, the OSC with the responsibility for the source zone will assume responsibility. This transfer of responsibility can initially occur verbally, with a follow-up of written documentation (enclosure 1). A source may be unknown or may occur in both Zones. In that case, the OSC for the Zone most significantly impacted will assume responsibility.

A seepage site should remain under the authority of the predesignated OSC for the zone that it is contained in. OSC responsibility may be transferred when the discharge or release crosses or has the potential to cross the boundary line, and the two agencies agree that the scope of potential and/or actual environmental impacts in one Zone significantly exceeds the other.

OSC Responsibility under the National Response Plan

During pollution responses during Incidents of National Significance under organizational structures of the National Response Plan (NRP), pollution impacts may affect many areas within the region. In these instances, OSC boundary designations may not be strictly adhered to in an effort to best use available resources to respond to the myriad of pollution issues under the guide of the NRP and Emergency Support Function (ESF) #10, if activated. However, under ESF #10, care shall be taken to place an OSC on an incident consistent with the parent agency's expertise. Where mutual agreement is not readily reached at the ESF-10 and OSC level in such cases, OSC responsibility will be determined by the Regional Response Team (RRT) co-chairs.

Nuclear/Radiological Incidents

Please consult the Nuclear-Radiological Incident Annex to the National Response Plan for guidance on coordinating agency and other agency roles in a nuclear or radiological incident. On-Scene Coordinator authorities and responsibilities apply to releases of radionuclides designated as hazardous substances (40 CFR 302.4), except where specifically excluded from the hazardous substance definition (statutory exclusions related to the Atomic Energy Act and Uranium Mill Tailings Radiation Control Act). While a radionuclide release may be fully addressed under the NCP under FOSC authority, there are a number of situation-dependent authorities, responsibilities, and coordinating functions of other federal agencies that may apply. The National Response Plan Nuclear-Radiological Incident Annex reconciles these roles by defining a coordinating agency based on the circumstances of an incident (Table 1 of the Annex), and further defining agency roles and responsibilities for both Incidents of National Significance and lesser incidents. OSCs should implement their NCP authority in a radionuclide release consistent with the coordination mechanisms of the NRP Nuclear-Radiological Incident Annex when an incident beyond NCP-only coordination occurs.

Notifications following Transfer of OSC Responsibility

EPA and the USCG often work closely with state and local counterparts during oil and hazardous substance pollution responses. To facilitate federal coordination with the state and local response community following a formal transfer of OSC responsibility, a signed copy of the transfer agreement should be sent to the appropriate state and/or local emergency response department. However verbal notification to the states is required as soon as the transfer of OSC responsibility takes place followed by the signed copy. The lead for enforcement actions may also be determined by the agency providing the OSC under other agreements and procedures; therefore, a copy of the transfer agreement should be sent to USCG and EPA enforcement personnel as appropriate to adjust enforcement lead.

Amendments and Effective Date

This agreement will be subject to review and amendment coincident with each periodic review of the Regional, Area, and other applicable contingency plans and any other time at the request of any of the parties. It will remain in effect until modified or terminated by mutual agreement.

5. POINTS OF CONTACT. Points of contact for the coordination, support, and implementation of this agreement are as follows:

Chief, Response and Prevention Branch
US EPA, Region 2 (MS-211)
2890 Woodbridge Avenue
Edison, NJ 08837-3679

Chief, Response Division
USCG First District
480 Atlantic Avenue
Boston, MA 02110

Chief, Response Division
USCG Fifth District
Federal Bldg.
431 Crawford Street
Portsmouth, VA 23704-5004

Chief, Response Division
USCG Ninth District
1240 East 9th St.
Cleveland, OH 44199-2060

Commander
Sector New York
212 Coast Guard Drive
Staten Island, NY 10305

Commander
Sector Delaware Bay
1 Washington Avenue
Philadelphia, PA 19147-4395

Commander
Sector Buffalo
1 Fuhrmann Blvd.
Buffalo, NY 14203-3189

Commander
Sector Long Island Sound
120 Woodward Ave.
New Haven, CT 06512-3698

Regional and Area Contingency Plans covering the States of New Jersey and New York will be amended to reflect the following geographical boundaries. This boundary agreement supersedes other agreements previously enacted concerning the federal pre-designated OSC boundaries for purposes of pollution response within federal Region 2.

6. OTHER PROVISIONS. Nothing in this Agreement is intended to conflict with current law or regulation or the directives of the United States Coast Guard or Department of Homeland Security or Environmental Protection Agency. If a term of this agreement is inconsistent with such authority, then that term shall be invalid, but remaining terms and conditions of this agreement shall remain in full force and effect.

7. EFFECTIVE DATE. The terms of this agreement will be come effective upon transmittal by the Co-Chairs of the Region 2 Regional Response Team.

8. MODIFICATION. This agreement may be modified upon the mutual written consent of the parties.

9. TERMINATION. The terms of this agreement, as modified with the consent of both parties, will remain in effect indefinitely. Either party upon 30 days written notice to the other party may terminate this agreement.

Statement of Agreement to Transfer Federal On-Scene Coordinator (OSC) Responsibility Between the U.S. Coast Guard (USCG) and U.S. Environmental Protection Agency (EPA) within Region 2 (excluding Caribbean)*

Pursuant to the Demarcation of the Inland/Coastal Zone Boundary for Region 2, this agreement documents that the (EPA/USCG) OSC hereby transfers responsibility to the (EPA/USCG) OSC to take response measures deemed necessary to protect the public health or welfare or environment from the below indicated threat or actual discharge or release:

at (location): _____

from (source): _____

on or about (time): _____, (date): _____ 20_____

and otherwise identified as (case name or number) _____

This transfer of responsibility is (check one):

❑ from USCG _____ to EPA Region _____
(Sector) (Region number)

—OR—

❑ from EPA Region _____ to USCG _____
(Region number) (Sector)

It is hereby agreed:

That this delegation of responsibility is limited solely to the aforementioned incident.

That this transfer of responsibility to the accepting OSC is COMPLETE and will include all associated investigation, cleanup or removal, disposal, public relations, enforcement, incidental paperwork, filing of required reports, and all other responsibilities of the OSC under the National Oil and Hazardous Substances Pollution Contingency Plan (NCP).

That this transfer will further remain in effect until such time as the accepting OSC has determined that there is no further danger to the public health or welfare.

That this agreement does not preclude continued mutual support between EPA and the USCG as deemed appropriate for this incident.

COAST GUARD Federal OSC	**EPA OSC**
DATE	**DATE**

* This document provided as a means, not the sole means, to document exchange of OSC responsibility. If this form is unavailable or OSCs are unable to exchange signatures due to incident circumstances, other communications can be used to effect and document a transfer.

GEOGRAPHIC AREAS OF FEDERAL RESPONSIBILITY
for
The States of NEW JERSEY and NEW YORK
(Inland and Coastal boundary demarcations)

In agreement between EPA Region II and USCG's Sector Delaware Bay, Sector New York, Sector Long Island Sound and Sector Buffalo, the following demarcation lines between the inland and coastal zones, for federal responsibility for response action, have been established for the states of New Jersey and New York.

State of New Jersey

The following is a geographic description of the points of demarcation between USCG and EPA Region II, for assuming Federal On-Scene Coordinator responsibilities in the State of New Jersey.

In New Jersey, the ***coastal zone*** includes:

1. The territorial seas adjacent to the COTP NY zone described in 33 CFR 3.05-30.
2. Hudson River: The entire length bordering New Jersey.
3. Hackensack River: Downstream of the Route 80 Bridge in ***Hackensack***.
4. Passaic River: Downstream of the 8th Street Bridge in ***Wallington***.
5. All of the Arthur Kill, Kill Van Kull and Newark Bay.
6. Raritan Bay and Sandy Hook Bay.
7. Raritan River: Downstream of the Albany Street Bridge (Route 27) in ***New Brunswick***.
8. All of the Navesink River.
9. Delaware River: From the Delaware Bay to the Alternate Route 1 Bridge (Bridge Street) in ***Trenton***.
10. Rancocas Creek: From the Delaware River to the I-295 Bridge in ***Willingboro***.
11. All of the Cooper River.
12. All of Newton Creek and its tributaries.
13. All of Little Timber Creek.
14. Big Timber Creek: From the Delaware River to the Route 42 Bridge.

15. Salem River: From the Delaware River to the Route 49 Bridge in ***Salem***.

16. Tuckahoe River: From Egg Harbor to the draw bridge at Route 50.

17. Great Egg Harbor River: From Great Egg Harbor to Routes 50 and 559 in ***Mays Landing***.

18. Mullica River: From Great Bay to Route 563.

The ***inland zone*** in the State of New Jersey includes the following waterways:

1. Delaware River: Upstream from the Alternate Route 1 Bridge (Bridge Street) in ***Trenton***.

2. Hackensack River: Upstream of the Route 80 bridge in ***Hackensack***.

3. Passaic River: Upstream of the 8th Street Bridge in ***Wallington***.

4. Raritan River: Upstream of the Albany Street Bridge (Route 27) in ***New Brunswick***.

5. Salem River: Upstream from the first bridge in ***Salem***.

EPA Region II will respond to spills inland of, and on the highway boundaries described below. The demarcation lines in the State of New Jersey between the inland and coastal response zones are as follows:

<u>From the NY/NJ Border, South to Fort Lee:</u>

The EPA/USCG boundary, from the New York/New Jersey border, begins with the Palisades Interstate Parkway and continues south to Route 95 in ***Fort Lee***.

<u>From Fort Lee, South to Bayonne/From Bayonne, North to Ridgefield Park (Hudson River, Newark Bay, East Side of Hackensack River):</u>

The boundary resumes south of Route 95 along Route 505 (Hudson Terrace), which becomes River Road, and continues on River Road into ***West New York***. In West New York, the boundary bears to the east at the intersection of River Road and Port Imperial Boulevard. It continues south along Port Imperial Boulevard into ***Weehawken***, where it bears south along Harbor Boulevard; then South on Route 677 (Park Ave) into ***Hoboken***. The boundary then continues east on Route 670 (14th Street); then south on Route 679 (Hudson Street); then west on Route 681 (Observer Highway); then south on Luis Munoz Marin Boulevard into ***Jersey City***. The boundary then continues east on 18th Street, which becomes Washington Boulevard; east on 2nd Street; then south on Hudson Street; west on Grand Street; south on the NJ Turnpike Extension, east on Audrey Zapp Drive into ***Liberty State Park***; then south on Freedom Way,

west on Morris Pesin Drive to the NJ Turnpike Extension. The boundary continues south on the NJ Turnpike Extension to Route 440, south on Route 440 to Route 501 (JFK Boulevard) in ***Bayonne***; then north on Route 501 to the NJ Turnpike Extension, west on the NJ Turnpike Extension to Route 440, north on Route 440 to Route 1 in ***Jersey City***. The boundary continues north on Route 1 to Route 653 (County Road) into Secaucus, then Northeast on Route 653 to I-95 (NJ Turnpike), then north on 1-95 to Route 80 in ***Ridgefield Park***.

From Ridgefield Park to Harrison (West Side of Hackensack River):

The boundary resumes west on I-95 to I-80; then west on I-80 to Hudson St; then south on Hudson St to Moonachie Rd; then south on Moonachie Road to Washington Ave; then south on Washington Ave to the NJ Tpk; then south on the NJ Tpk to the Newark Pike.

From Harrison, North to Passaic/From Passaic, South to Newark (Passaic River):

The boundary continues west on the Newark Pike to Passaic Ave; then north on Passaic Ave which becomes River Rd/Riverside Ave/Jackson Ave/Carlton Ave to Locust Ave; then north on Locust Ave to 8th St; then north on 8th St to Passaic St. then west on Passaic St to Route 21; then south on Route 21 to Raymond Blvd; then east on Raymond Blvd to the NJ Turnpike.

From Newark to New Brunswick (Newark Bay, Arthur Kill, North Side of Raritan River):

The boundary continues south on the NJ Turnpike to Route 514 near ***Fords***; then west on Route 514 to Route 27; then south on Route 27 to Route 18 to ***New Brunswick***.

From New Brunswick to South Amboy (South Side of Raritan River):

The boundary continues south on Route 18 to Route 535; then east on Route 535 to Route 670 in ***Sayreville***; then east on Route 670 to Route 9 in ***South Amboy***.

From South Amboy, south to Long Branch (End of Sector NY AOR):

The boundary continues south on Route 9 to Route 35 South; and continues south on Route 35 to the vicinity of ***Eatontown***, where it reaches the southern boundary of Sector NY's AOR at 40°18'N latitude.

From Long Branch, south to Cape May (Begin Sector Delaware Bay AOR):

The boundary continues south on Route 35 to Route 70 in ***Brielle***; then south on Route 70 to Route 549; then south on Route 549 to Route 37; then west on Route 37, then south on Route 166 in ***Toms River*** to Route 9 South. The boundary continues south along Route 9 south to the Garden State Pkwy in ***Somers Point***; then south on the Garden State Pkwy to Route 47 in ***Rio Grande***.

From Trenton, South to Cape May:

The EPA/USCG boundary begins at the US Highway 1 Bridge between ***Morrisville, PA*** and ***Trenton, NJ***; continues east to its intersection with Route 29 South in ***Trenton***; then south along Route 29, which becomes Route 29/129, and merges into Interstate 195. The boundary continues on I-195 to its junction with Route 206 in the vicinity of ***White Horse***; then south on Route 206 to Route 130 in ***Bordentown***. The boundary then continues south on Route 130 to Route 49 in the vicinity of ***Deepwater***; then continues on Route 49 south and east, to its junction with Route 47 in ***Millville***. The boundary then continues south on Route 47, to its junction with the Garden State Parkway in the vicinity of ***Rio Grande***.

State of New York

The following is a geographic description of the points of demarcation between USCG and EPA Region II, for assuming Federal On-Scene Coordinator responsibilities in the State of New York.

Southeast New York State:

The ***coastal zone*** in the ***southeast region*** of New York State is described as:

1. The territorial seas adjacent to the COTP NY zone described in 33 CFR 3.05-30.

2. All of Lower Bay, Jamaica Bay, Gravesend Bay, East Rockaway Inlet, Coney Island Channel and tributaries south of the Belt Parkway on Long Island.

3. All of Upper Bay, The Narrows, Gowanus Bay, Gowanus Creek Channel, Bay Ridge Channel, Red Hook Channel, and Buttermilk Channel.

4. All of the Arthur Kill, Kill Van Kill and Newark Bay.

5. Hudson River (aka North River), from New York Bay to the Route 7 bridge in ***Green Island***.

6. All of the East River, Harlem River, and Spuyten Duyvil Creek, and Newtown Creek west of the Pulaski Bridge.

7. Westchester Creek, Bronx River, Eastchester Bay, Hutchinson River (aka Eastchester Creek), Flushing Bay and Creek, Little Bay, Little Neck Bay, Manhasset Bay, Hempstead Harbor and that portion of Long Island Sound west of a line drawn between the Connecticut/New York border and Dosoris Island on Long Island and north of Northern Blvd (Route 25A) on Long Island.

EPA Region II will respond to spills inland of, and on the highway boundaries described below. The demarcation lines between the inland and coastal response zones in the southeastern portion of the State of New York are as follows:

From the NY/NJ Border, West of the Hudson River, Northward:

The boundary between EPA and USCG begins on the Palisades Interstate Parkway; continues north on Route 9W to Interstate 787 in ***Albany***; then north on I-787 to Route 7 in ***Green Island***.

East of the Hudson River, From Green Island, Southward to the Bronx/Westchester County:

The boundary continues from the Route 7 bridge, to River Street in ***Troy***; then south on River Street, to the intersection with Front Street; then south on Front Street, to 1st Street; then south on 1st Street, to Madison Street; then west on Madison Street, to the CSX rail line. The boundary then continues along the CSX rail line, south along the eastern bank of the Hudson River, to the

intersection with Route 9 (Broadway) in the ***Bronx***. The boundary continues northeast on Route 9 to West 225th Street; then east on West 225th Street to the intersection with Route 87 (Major Deegan Expressway); then south on Route 87 to the intersection with Route 278 (Bruckner Expressway). The boundary then continues northeast on Route 278 to Route 95; then north on Route 95 to the Connecticut border.

Island of Manhattan:

The boundary begins on the northern tip of Manhattan on the Henry Hudson Parkway (Route 9A) and continues south on the Henry Hudson Parkway - which subsequently becomes the West Side Highway, West Street, and South Street - to the southern tip of Manhattan. The boundary then continues along the FDR Drive, which becomes the Harlem River Drive, to Dyckman Street, back to the intersection with the Henry Hudson Parkway.

Long Island (Brooklyn; Queens; Nassau and Suffolk Counties):

The boundary begins on the western end of the island at the Verrazano Narrows Bridge, and continues east along the Belt Parkway (Route 27) to the intersection with Merrick Road (Route 27A) in ***Rockville Center***; then east along Merrick Road, which becomes Montauk Highway at the ***Nassau/Suffok County*** border; then east along Montauk Highway to the intersection with Route 104 in the vicinity of ***Quogue***. The boundary then continues north on Route 104 to the intersection with Route 63 in ***Riverhead***; then north on Route 63 to Route 25; then west on Route 25 to the intersection with Route 25A in the vicinity of ***Calverton***. The boundary then continues west on 25A to the intersection with McGuinness Boulevard in ***Queens***; then south on McGuinness Boulevard to the Brooklyn-Queens Expressway (Route 278); then south on the Brooklyn-Queens Expressway to the Belt Parkway in ***Brooklyn***; then along the Belt Parkway back to the Verrazano Narrows Bridge.

Staten Island:

The boundary begins at the Outerbridge Crossing (Route 440) and proceeds north on Arthur Kill Road to the intersection with Route 440 in the Rossville section; then north on Route 440 to the intersection with Route 278. The boundary continues west on Route 278 to Western Avenue; then north on Western Avenue to Richmond Terrace; then east on Richmond Terrace to the ***St. George*** section, where Richmond Terrace becomes Bay Street. The boundary continues south on Bay Street to School Road; then southwest on School Road to Lily Pond Road; then south on Lily Pond Avenue to Father Capodanno Boulevard. The boundary continues southwest on Father Capodanno Boulevard to Greeley Avenue; then northwest on Greeley Avenue to Hylan Boulevard; then southwest on Hylan Boulevard to Craig Avenue. The boundary continues north on Craig Avenue to Bentley Street; then northwest on Bentley Street to Arthur Kill Road; then north on Arthur Kill Road back to the Outerbridge Crossing (Route 440).

The ***inland zone*** in the State of New York includes the following waterways:

1. Hudson River: From the Route 7 bridge in ***Troy***, north on the New York State Barge Canal system to Lake Champlain.

2. Lake Champlain: Those waters within the territorial boundary of New York State.

3. Mohawk River & the New York State Barge Canal: From the Hudson River west to ***Lockport***.

Northern New York State:

The ***coastal zone*** in northern New York State includes the following waterways inland of the boundary line, as described below:

1. Smokes Creek: Upstream past the confluence of the south and north branches of Smokes Creek, to the Route 62 bridges over the south and north branches of Smokes Creek, in the town of ***Lackawanna***.

2. The Union Canal: In the city of ***Buffalo***.

3. The Buffalo River: Upstream to the confluence with Cazenovia Creek at the Bailey Avenue (Route 62)/Hussey Street bridges in the city of ***Buffalo***.

4. The U.S. portion of the Niagara River and all of Grand Island.

5. The Scajaquada Creek: Upstream to the Grant Street bridge, in the City of ***Buffalo***.

6. New York State Barge Canal (formerly Erie Barge Canal) and Ellicott Creek: Elicott Creek upstream to the Young Street/Arterial Highway bridge in the city of ***North Tonawanda***. The New York State Barge Canal east to Lock 34 in the town of ***Lockport***.

7. 18 Mile Creek: Upstream to Burt Dam in the town of ***Burt***.

8. Oak Orchard Creek: Upstream to the Route 18 Bridge.

9. Sandy Creek at Sandy Harbor Beach: Upstream to Route 19 (Lake Road East Fork).

10. Bradock Bay including the north branch of West Creek: Upstream to Route 261 (Manitou Road).

11. The Genesee River: Upstream to its confluence with the New York State Barge

Canal at the Interstate 390 bridge, in the city of ***Rochester***.

12. All of Irondequoit Bay south to the Route 404 bridge, in the city of ***Rochester***.

13. All of Sodus Bay south to Route 104, in the town of ***Sodus***.

14. The Oswego River: South to Lock 8 in the town of ***Oswego***.

15. The Salmon River: Upstream to the town of ***Pulaski***.

16. French Creek Bay: Upstream to French Creek.

EPA Region II will respond to spills inland of, and on the highway boundaries described below. The demarcation lines between the inland and coastal response zones in the northern portion of the State of New York are as follows:

The boundary between EPA and USCG begins at Route 5 on the Pennsylvania/New York State boundary; then continues north and east along NY Route 5 to Interstate 190 North in the city of ***Buffalo***.; then north along Interstate 190 to Route 266 (River Rd), in the town of ***Tonawanda***. The boundary continues north along Route 266 to 265/384 (River Rd), in city of Tonawanda; then north and west along Route 265/384 (River Road) to its intersection with the La Salle Expressway in the city of ***Niagara Falls***; then west along the La Salle Expressway to the Robert Moses Parkway in the city of Niagara Falls.

The boundary continues west and north along the Robert Moses Parkway to Route 104, in the town of ***Lewistown***; then west along Route 104 to Route 18F (Lower River Road/Lake Road); continues north and west along Route 18F to its junction with Route 18 in the town of ***Porter***; then east along Route 18 to the intersection with the Lake Ontario Parkway at Lake Side State Park in the town of ***Kuckville***. The boundary continues east along the Lake Ontario State Parkway to the Genesee River; then east on Lake Shore Blvd, on the east bank of the Genesee River, to Irondequoit Bay; continues east along Route 101 Lake Road, on the east bank of Irondequoit Bay, to Sodus Bay; then east along Route 104, on the east bank of Sodus Bay, to Route 104A in the town of ***Wolcott***.

The boundary continues east along Route 104A to Route 104 in ***Oswego***; then east along Route 104 to the Oswego River; then continues east on Route 1 (North Road) on the east bank of the Oswego River, to Route 104B; then east on Route 104B East to Route 3 in the town of ***Mexico***. The boundary continues north along Route 3 to Route 180 at the Dexter Marsh Wildlife Management Area; continues north and east on Route 180 to Route 12E, in the Town of ***Limerick***; then north and west along Route 12E to the town of ***Cape Vincent***.

The boundary continues east along 12E, to French Creek Bay; then east on Route 12, on the east bank of French Creek Bay, to Route 37 in the town of ***Morristown***. The boundary continues northeast along Route 37 to the town of ***Hogansburg***, where Route 37 crosses the St. Regis River. The boundary then continues north along the east bank of the St. Regis River, to the St. Lawrence River to the international border with Canada.

MEMORANDUM OF AGREEMENT (MOA) BETWEEN
U.S. ENVIRONMENTAL PROTECTION AGENCY - REGION III AND
U.S. COAST GUARD - FIFTH DISTRICT

Purpose

The intent of this Memorandum between the United States Environmental Protection Agency (EPA), Region III and the United States Coast Guard (USCG), Fifth District is to delineate the Region III Inland and Coastal Zone geographical boundaries establishing responsibility for the On-Scene Coordinator (OSC) for pollution response, pursuant to the Clean Water Act, as amended, (CWA), 33 U.S.C. §§ 1251 - 1387; and the National Oil and Hazardous Substances Contingency Plan (NCP), 40 C.F.R. §§ 300.5 and 300.120.

Definitions

The following definitions will apply to this Memorandum of Agreement (MOA):

Vessel - Every description of watercraft or other artificial contrivance used, or capable of being used, as a means of transportation on water. This definition excludes permanently moored structures, which, while they may appear to be vessels are not inspected by the Coast Guard, i.e., barges moored at facilities effectively used as part of a non-transportation-related facility complex.

Commercial Vessel - As defined in this MOA, commercial vessel means tank vessels (ships and barges); freight ships and barges; commercial fishing vessels; inspected passenger vessels; and uninspected towing vessels. This definition excludes recreational vessels and uninspected passenger vessels carrying six or fewer persons for hire.

Marine Transportation-Related Facility (MTR Facility) - Any onshore facility or segment of a complex regulated under section 311 (j) of the Federal Water Pollution Control Act by two or more Federal agencies, including piping and any structure used or intended to be used to transfer oil to or from a commercial vessel. The marine transportation-related portion of the complex extends from the facility oil transfer system's connection with the commercial vessel to the first valve inside the secondary containment surrounding tanks in the non-transportation-related portion of the facility or, in the absence of secondary containment, to the valve or manifold adjacent to the tanks comprising the non-transportation-related portion of the facility, unless another location has been agreed to by the USCG Captain of the Port (COTP) and the appropriate Federal official.

U.S. Environmental Protection Agency
Region III
1650 Arch Street
Philadelphia, PA 19103-2029

Commander (dr)
Fifth Coast Guard District
431 Crawford Street
Portsmouth, VA 23704

Facility – means (1) a Facility, as defined by Section 101(9) of Comprehensive Environmental Response, Compensation and Liability Act, as amended (CERCLA), 42 U.S.C. § 9601(9), to mean any building, structure, installation, equipment, pipe or pipeline (including any pipe into a sewer or publicly owned treatment works), well, pit, pond, lagoon, impoundment, ditch, landfill, storage container, motor vehicle, rolling stock, or aircraft, or any site or area, where a hazardous substance has been deposited, stored, disposed of, or placed, or otherwise come to be located; but does not include any consumer product in consumer use or any vessel (*CERCLA Facility*), as well as (2) a Facility, as defined by Section 1001(9) of the Oil Pollution Act (OPA), and Section 311(a)(10) and (11) of the Clean Water Act, as amended (CWA), 33 U.S.C. §§ 2710(9) and 1321(a)(10) and (11), to mean any structure, group of structures, equipment, or device (other than a vessel) which is used for one or more of the following purposes: exploring for, drilling for, producing, storing, handling, transferring, processing, or transporting oil, and this term includes any motor vehicle, rolling stock, or pipeline used for one or more of these purposes (*OPA Facility*).

Pollution Response – means a "removal" of a "discharge" of "oil," as those terms are defined in Section 311(1), (2) and (8) of the CWA and Section 1001(7), (23) and (30) of the OPA, as well as a "response" to a "release" of "hazardous substances," as those terms are defined by Section 101(14), (22) and (25) of CERCLA.

Road - For boundary sections that are designated by the use of the median strip as the line on roads, the Inland Zone shall include the median strip.

Riverbank - The land along the edge of a river, which is at the level of the mean high water mark.

Tide - The periodic variation in the surface level of the oceans and of bays, inlets, and tidal regions of rivers, which is at the level of the mean high water mark.

Inland/Coastal Zone Boundary Designation

EPA Region III provides the OSC for pollution response in the Inland Zone. The cognizant USCG COTP is the pre-designated OSC for pollution response in the Coastal Zone, as defined in the NCP, 40 C.F.R. § 300.5.

Precise boundaries are determined by EPA/USCG agreements and identified in federal regional contingency plans. The Inland and Coastal Zone geographical boundaries for Region III can be found in Attachment A (Written Boundaries) and Attachment B (Geographical Boundaries).

General Response Provisions

These provisions apply to all EPA OSCs and USCG COTP/OSCs serving Federal Region III. In Region III, the EPA and USCG will carry out agency and specific pollution response responsibilities under the NCP, the Regional Contingency Plan (RCP), and the applicable Area Contingency Plan (ACP), and will assist each other to the fullest extent

possible to prevent or minimize the impacts of an actual discharge or release, or a substantial threat of such a discharge or release, of an oil or hazardous substance where each respective agency has jurisdiction.

The designated boundary lines are intended to delineate the area of responsibility for federal response action to a discharge of oil or a release of a hazardous substance within Federal Region III and describe the transition point from the Coastal Zone (USCG jurisdiction) to the Inland Zone (EPA jurisdiction). For ease, boundaries were drawn following roads, state boundaries, and other landmarks and, as a general rule, the location of the source of the discharge in relation to the boundary will be the determining factor of which agency provides the OSC. However, this MOA recognizes the USCG's primary mission and expertise over discharges and releases in or threatening navigable waters subject to the tide, and EPA's primary mission and expertise for discharges and releases that occur on or threaten land and non-tidal, navigable waters. Therefore, the boundaries do not preclude one agency from transferring to the other agency OSC responsibilities for releases and/or discharges which occur within its zone, as set forth below.

The USCG, through the cognizant COTP, will assist the Inland Zone EPA OSC, consistent with applicable agency responsibilities and authorities. The USCG COTP will assume the role of OSC in response to an incident in the Inland Zone when it involves a commercial vessel, a commercial vessel transfer operation, the MTR portion of a facility, and results in an actual discharge or threatened discharge of oil or release of a hazardous substance into or on the navigable waters of the United States, its shoreline or the riverbank.

The EPA, through the EPA OSC, will assist the Coastal Zone USCG OSC, consistent with applicable agency responsibilities and authorities. The EPA will assume the role of OSC in response to an incident in the Coastal Zone when it involves a CERCLA and/or OPA Facility and results in an actual or threatened discharge of oil, or an actual or threatened release of a hazardous substance, that occurs on or threatens land and non-tidal, navigable waters.

The designated boundary lines do not preclude mutual assistance between the two agencies. Either agency can request the other to become the OSC when the requesting (lead) agency believes that the other agency can respond more effectively. The lead agency can request the other agency to determine whether it has the expertise and resources to mount an effective response, and accept or decline the request to serve as the OSC. Transferring Federal OSC authority from one agency to another can be done by verbal agreement between an EPA OSC and the USCG COTP. This verbal agreement shall be documented in a Pollution Report (POLREP) from the agency taking over the Federal OSC authority within 30 days of this verbal agreement.

Regardless of any agreements within this MOA, it is the responsibility of the EPA (for all Inland Zone responses) and the USCG (for all Coastal Zone responses) to ensure that the other agency (EPA or USCG) has properly taken over OSC responsibilities in its zone prior to relieving itself of any OSC responsibility.

Amendments and Effective Date

This agreement will be subject to review and amendment coincident with each periodic review of the Regional, Area, and other applicable contingency plans and any other time at the request of either of the parties. This document may be cancelled in whole or in part by any party thereto. Any cancellation will take place 30 days following delivery of written notification to EPA or USCG. It will remain in effect until modified or terminated by mutual agreement.

Requests or recommendations for modification to the Inland/Coastal boundary delineations or modifications to this MOA shall be referred to EPA Region III and USCG Fifth District prior to consideration. Those points of contact shall be:

- EPA Region III - Associate Division Director, Office of Preparedness and Response, Philadelphia, PA at (215) 814-3241; EPA's 24 hour number: (215) 814-3255;

- Fifth Coast Guard District - Chief, Response Division, Portsmouth, VA at (757) 398-6676; USCGD5's 24 hour number: (757) 398-6231.

Regional and Area Contingency Plans of the signatory agencies will be amended to reflect the following geographical boundaries and agreements contained herein. This MOA supercedes other MOAs previously in effect concerning the federal OSC boundaries for purposes of pollution response within Federal Region III. This document is effective upon the date that it is fully executed by both parties.

Date: 1/6/10

Kathryn A. Hodgkiss
Acting Division Director
Hazardous Site Cleanup Division
U.S. EPA Region III
Philadelphia, PA

Date: 1/5/10

CAPT Michael J. Andres
Commander (dr)
Fifth Coast Guard District
Portsmouth, VA

Attachment A

Written Boundary

Sector Baltimore

Start at a point latitude 38°27'15" N, longitude 75°30'00" W. on the Delaware-Maryland boundary, proceeding along the Delaware-Maryland boundary west to a point at latitude 38°27'37" N, longitude 75°41'35" W and north to the Pennsylvania boundary at a point latitude 39°43'22" N, longitude 75°47'17" W; thence west along the Pennsylvania-Maryland boundary to the West Virginia boundary at a point latitude 39°43'16" N, longitude 79°28'36" W; thence south and east along the Maryland-West Virginia boundary to the intersection of the Maryland-Virginia-West Virginia boundaries at a point latitude 39°19'17" N, longitude 77°43'08" W; thence southwest along the Loudoun County, VA boundary to the intersection with Fauquier County, VA at a point latitude 39°00'50" N, longitude 77°57'43" W; thence east along the Loudoun County, VA boundary to the intersection with the Prince William County, VA boundary at a point latitude 38°56'34" N, longitude 77°39'18" W; thence south along the Prince William County boundary to the intersection with Stafford County, VA, at a point latitude 38°33'22" N, longitude 77°31'52" W; thence east along the Prince William County, VA boundary to a point near the western bank of the Potomac River at latitude 38°30'11" N, longitude 77°18'01" W; thence south and east along the southern bank of the Potomac River to the Maryland-Virginia boundary at a point latitude 37°53'25" N, longitude 76°14'12" W; thence east along the Maryland-Virginia boundary as it proceeds across the Chesapeake Bay, Tangier and Pocomoke Sounds, Pocomoke River, and Delmarva Peninsula to a point on the Maryland-Virginia boundary near the Atlantic coast at latitude 38°00'18" N, longitude 75°30'00" W; thence north to the Delaware-Maryland boundary at the point of origin.

Sector Delaware Bay

North along State Highway 113 from the MD/DE state line to its intersection with US 9 in DE; then northward along US 9 to the southern bank of the Chesapeake and Delaware Canal (C & D Canal); then westward along the southern bank to the DE/MD state line, and then eastward along the northern bank of the C & D Canal to US 9, and then north along US 9 to its intersection with 1-495; then northward along 1-495 to its intersection with 1-95 at the PA/DE border; then northward along 1-95 to the Schuylkill River, and then along the high tide mark of the Schuylkill River to the dam at Fairmont Park, and then northward on I-95 to its intersection with US Highway 1; then northward along US Highway 1 to the US Highway 1 bridge between Morrisville, PA and Trenton, NJ.

Sector Hampton Roads

The southern boundary extends from the offshore extent of the Exclusive Economic Zone at 34-59.8N, 071-28.0W shoreward along 34-59.8N to the VA/NC border. Then along the border to the west bank of the Dismal Swamp canal; north along the west bank of the Hwy.13 to State Hwy. 10, along State Hwy. 10 to State Hwy. 156; then north along State Hwy. 156 over the Benjamin Harrison Highway Bridge in Hopewell, VA, to State Hwy.5; then east on Interstate 64; then west on U.S. Interstate 64 to State Hwy 30; north on State Hwy. 30 to State Hwy. 33; east on State Hwy. 33; west on State Hwy. 33 to U.S. Route 17; north on U.S. route 17 to State Hwy. 360; east on State Hwy. 360 across the bridge in Tappahannock, VA. To State Hwy. 3; south on State Hwy.3 to State Hwy.200; north on State Hwy. 200 to State Hwy.360; west on State Hwy. 360 to State Hwy. 202; north on State Hwy. 202 to State Hwy. 3; west on State Hwy 3 to State Hwy. 205; north along State Hwy 205 to State Hwy. 218; north along Hwy. 218 to State Hwy 301; east along State Hwy. 301 to the west bank of the Potomac River; east along the VA-MD border; across the eastern shore then out to sea to the offshore extent of the Exclusive Economic Zone.

Attachment B

Geographical Boundary

Annex DD

Federal Agencies Who Can Support the FOSC

Federal Agencies

Who Can Support the FOSC

Federal Agency Scientific/Technical Support

U. S. Coast Guard (USCG)

- **The National Strike Force Coordination Center (NSFCC)**
  The NSFCC manages the NSF which is authorized as the National Response Unit required under OPA, with responsibility for administering the USCG Strike Teams, and maintaining response equipment inventories and logistical networks. The NSFCC offers the technical assistance and equipment for spill response, assistance in coordinating resources during oil discharge response, Area Contingency Plan (ACP) or Regional Contingency Plan (RCP) review, coordination of spill response resources information, and inspection of Oil Spill Removal Organization (OSRO) response equipment. Strike Teams provide trained personnel and specialized equipment to assist the FOSC in training for spill response, stabilizing and containing the spill, and monitoring or directing response actions of the responsible parties (RPs) and/or contractors.

- **The USCG National Strike Force (NSF)**
  The NSF's mission is to provide highly trained, experienced personnel and specialized equipment to the Coast Guard and other federal agencies to facilitate preparedness and response to oil and hazardous substance pollution incidents in order to protect public health and the environment. The NSF's area of responsibility (AOR) covers all Coast Guard Districts and Federal Regions.

- **USCG Strike Teams (Atlantic, Gulf, and Pacific)**
  The three USCG Strike Teams are available 24 hours a day. If the Strike Team contacted is already committed, another Strike Team will be deployed. Each Strike Team maintains trained personnel and specialized equipment to assist with training in responding to spills, stabilizing and containing spills, and monitoring and/or directing response actions of the RPs and/or contractors. The Atlantic Strike Team, based at Fort Dix in New Jersey, provides response coverage to the Delaware Bay AOR.

- **Public Information Assist Team (PIAT)**
  PIAT is an element of the NSFCC staff available to assist the FOSC to meet the demands for public information during a response or exercise. PIAT provides interagency crisis communication team(s) and technical expertise to assist ICs and FOSCs meet their objectives of truth and transparency of operations for the public. PIAT provides emergency risk communication support to ICs and FOSCs during incidents such as oil spills, hazardous substance releases, hurricanes, floods, or other disasters. Its use is encouraged any time the FOSC requires outside public affairs support. Requests for PIAT assistance may be made through the NSFCC or National Response Center (NRC). See the Spill of National Significance (SONS) Public Affairs Reference for more information.

- **Incident Management Assistance Team (IMAT)**
  The IMAT was developed by the USCG to supply a ready-made team of highly trained individuals to assist the local Incident Command (IC) in dealing with a major incident. The IMAT is located in Norfolk, VA. The team is trained for initial quick response to a regionally or nationally significant event. The team consists of Incident Command Systems (ICS) process experts that can quickly set-up and assist in transitioning from the initial emergency phase to a more sustained planning process. The IMAT deploys with a limited amount of equipment to ensure ICS functionality within an Incident Command Post (ICP).

- **National Pollution Funds Center (NPFC)**
  NPFC is responsible for implementing those portions of OPA Title I delegated to the Secretary of the Department in which the USCG is operating. NPFC is responsible for addressing funding issues arising from actual and potential discharges of oil. Responsibilities of the NPFC include:
    1. issuing Certificates of Financial Responsibility (COFRs) to owners and operators of vessels to pay for costs and damages incurred by their vessels as a result of oil discharges,
    2. providing funding to various response organizations for timely abatement and removal actions related to oil discharges,
    3. providing equitable compensation to claimants who sustain costs and damages from oil discharges when the RP fails to do so,
    4. recovering monies from persons liable for costs and damages resulting from oil discharges to the full extent of liability under the law, and
    5. providing funds to initiate Natural Resource Damage Assessment (NRDA) activities.

- **USCG District Response Advisory Team**
  USCG's Fifth District Response Advisory Team (DRAT) and the Incident Management and Preparedness Advisor (IMPA) provide pollution planning, preparedness, and response policy guidance and assistance to an FOSC and staff on a regular basis.

- **USCG (SecDelBay) Marine Transportation System Recovery Unit (MTSRU)**
  MTSRU assists the FOSC in restoring port functions and resuming commercial activity as quickly as possible. MTSRU is the mechanism to prepare for and conduct recovery operations, mitigate the effects of a port closure and enhance the speedy recovery of the port back to normal operations.

Environmental Protection Agency

- **Environmental Response Team (ERT)**
  In the event of a continuing release or discharge, the FOSC has access to EPA's ERT, stationed in Edison, New Jersey; Cincinnati, Ohio; Erlanger, Kentucky; Las Vegas, Nevada; and Research Triangle Park, North Carolina. The ERT provides Scientific Support Coordinators (SSC) with expertise in treatment technology, biology, chemistry, hydrology, geology, and engineering. The ERT also has access to special decontamination equipment and can provide advice on a wide range of issues such as a multimedia sampling and analysis program, on-site safety (including development and implementation plans), cleanup techniques and priorities, water supply decontamination and protection, application of dispersants, environmental assessment, degree of cleanup required, and disposal of contaminated material. The FOSC may designate an SSC as principal advisor on scientific issues who also communicates with the scientific community and assists in requests to state and federal agencies.

- **Chemical, Biological, Radiological, and Nuclear (CBRN) Consequence Management Advisory Division (CMAD)**
  The CBRN CMAD, present at five geographic locations, provides 24/7 scientific and technical expertise to the FOSC or response customer for all phases of consequence management. With a focus on operational preparedness, CBRN CMAD facilitates the transition of the latest science and technology to the field response community in order to provide tactical options for screening, sampling, monitoring, decontamination, clearance, waste management, and toxicological/exposure assessment during decontamination of buildings or other structures following an incident involving releases of radiological, biological, or chemical contaminants. CBRN CMAD maintains critical partnerships with: (1) EPA's National Homeland Security Research Center and the EPA's special teams; (2) other federal partners including the U.S. Department of Homeland Security (DHS), Federal Bureau of Investigation, DOD, and Centers for Disease Control and Prevention (CDC)/Department of Health and Human Services (HHS); and (3) international partners.

- **Radiological Emergency Response Team (RERT)**
  RERTs have been established by EPA's Office of Radiation Programs (ORP) to provide response and support during incidents or at sites containing radiological hazards. Expertise is available in radiation monitoring, radionuclide analysis, radiation health physics, and risk assessment. RERTs can provide on-site support including mobile monitoring laboratories for field analysis of samples as well as fixed laboratories for radiochemical sampling and analyses. Request for support may be made 24 hours a day via the NRC or directly to the EPA Radiological Response Coordinator in the ORP.

National Oceanic and Atmospheric Administration (NOAA)

NOAA provides scientific support for responses and contingency planning in coastal and marine areas, including assessments of the hazards that may be involved, predictions of movement and dispersion of oil and hazardous substances through trajectory modeling, and information on the sensitivity of coastal environments to oil or hazardous substances. NOAA provides scientific expertise on living marine resources it manages and protects. It also provides information on actual and predicted meteorological, hydrologic, ice, and oceanographic conditions for marine, coastal, and inland waters, as well as, tide and circulation data. The Secretary of the U.S. Department of Commerce (DOC), through NOAA, also acts as trustee for natural resources managed or controlled by DOC, including their supporting ecosystems.

- **Scientific Support Coordinators (SSC)**
  The SSC, in accordance with the National Contingency Plan (NCP), will provide the FOSC scientific advice with regard to the best course of action during a spill response. The SSC will help facilitate consensus from the Federal natural resource management agencies and provide spill trajectory analysis data, information on the resources at risk, weather information, tidal and current information, etc. The SSC will be the point of contact for the Scientific Support Team from NOAA's Hazardous Material Response and Assessment Division. The FOSC's Guide to NOAA Scientific Support outlines all of the products and services the NOAA SSC can provide for planning and response activities. The NOAA SSC can provide training and technical expertise with SCAT. The Shoreline Assessment Manual, updated August 2013 by NOAA/HAZMAT, outlines methods for conducting shoreline assessment after an oil spill.

- **National Weather Service (NWS)**
  NWS, a federal organization within NOAA, can provide various types of support to an Incident Command (IC)/Unified Command (UC) operating in Sector Delaware Bay area of responsibility The IC/UC will be provided with a direct unlisted number to the lead forecaster's desk, through which continuous information on wind speeds, temperatures, and other atmospheric data can be obtained.

U.S. Department of the Interior (DOI)

DOI has jurisdiction over the National Park System, National Wildlife Refuges, fish hatcheries, and public lands. The Regional Environmental Officer (REO) manages the department's response programs for oil and hazardous substance spills and oversees the department's responsibilities as a trustee for natural resources. The DOI may become involved in spill response

once contacted through the REO who is a designated member of RRT-3. The REO for RRT-3 is located in Philadelphia, PA.

- **U.S. Fish and Wildlife Service (USFWS)**
  The Secretary of the Interior acts as trustee for resources managed or protected by DOI Bureaus, including USFWS and Bureau of Reclamation (USBR). USFWS, an office within DOI, is responsible for the management of migratory birds, federally listed endangered and threatened species, and interjurisdictional fishes within SecDelBay AOR. National Wildlife Refuge lands established in/near the ACP planning area include:
    - John Heinz National Wildlife Refuge
    - Edwin B. Forsythe National Wildlife Refuge
    - Supawna Meadows National Wildlife Refuge
    - Cape May National Wildlife Refuge
    - *Note: States have several State Wildlife Management Areas.*

  When a spill occurs, the appropriate USFWS office(s) will provide timely advice on measures necessary to protect wildlife from exposure, as well as priority and timing of such measures. Protective measures may include preventing the oil from reaching areas where migratory birds and other wildlife are located or deterring birds or other wildlife from entering areas by using wildlife hazing devices or other methods.

  If exposure of birds and other wildlife to oil or hazardous substances cannot be prevented, an immediate decision will be made regarding rescue and rehabilitation of "oiled" birds and other wildlife. Decisions to rescue and rehabilitate "oiled" wildlife must be made in conjunction with other federal and state natural resource management agencies. Wildlife rehabilitators will need federal, and state permits to collect, possess, and band migratory birds and threatened/endangered species.

  For more information see the Fish and Wildlife and Sensitive Environments Plan (FWSEP), Annex 28 and the Wildlife Response Plan, Annex 28a of the RRT-3 RCP.

- **U.S. Geological Survey (USGS)**
  USGS maintains expertise in water quality characterization, oil fingerprinting, submerged oil and oil-particle formation, transport and resuspension of oil in fresh waters, riverine two-dimensional (2D) particle transport/hydrodynamic simulations, ecotoxicology, time-of-travel studies for freshwater systems, and geospatial data collection of visible spill plumes applicable to spill response events in freshwater environments. In addition, USGS can provide biological survey assistance for natural resources and contaminants and contribute distribution information about sensitive species (e.g., birds, invertebrates). USGS also provides extensive expertise and information for natural resource damage assessments (NRDAs) (e.g., aerial

surveys, abundance estimation, remote sensing, etc.).

- **Bureau of Safety and Environmental Enforcement (BSEE)**
  BSEE works to promote safety, protect the environment, and conserve resources offshore through vigorous regulatory oversight and enforcement. BSEE's Offshore Regulatory Program develops standards and regulations to enhance operational safety and environmental protection for the exploration and development of offshore oil and natural gas on the U.S. Outer Continental Shelf (OCS).

U.S. Department of Health and Human Services (HHS)

HHS through the Agency for Toxic Substances and Disease Registry (ATSDR), serves the public by using the best science, taking responsive public health actions, and providing trusted health information to prevent harmful exposures and disease related to toxic substances. The ATSDR is directed by congressional mandate to perform specific functions concerning the effects on public health of ***hazardous substances*** in the environment. These functions include public health assessments of waste sites, health consultations concerning specific hazardous substances, health surveillance and registries, response to emergency release of hazardous substances, applied research in support of public health assessments, information development and dissemination, and education and training concerning hazardous substances.

Public Health Technical Specialists from the HHS Centers for Disease Control and Prevention (CDC) and ATSDR can assist with environmental health support.

- **The National Institute for Occupational Safety and Health (NIOSH)**
  NIOSH provides national and world leadership to prevent work-related illness, injury, disability, and death by gathering information, conducting scientific research, and translating the knowledge gained into products and services, including scientific information products, training videos, and recommendations for improving safety and health in the workplace.

In response to requests from workers (or their representatives), employers, and other government agencies, NIOSH Health Hazard Evaluation scientists conduct workplace assessments to determine if workers are exposed to hazardous materials or harmful conditions and whether these exposures are affecting worker health. NIOSH evaluates the workplace environment and health of employees by reviewing records and conducting on-site environmental sampling, epidemiologic surveys, and medical testing.

See the NIOSH Pocket Guide for more information.

U.S. Department of Agriculture (USDA)

USDA has scientific and technical capability to measure, evaluate, and monitor, either on the ground or by use of aircraft, situations where natural resources including soil, water, wildlife, and vegetation have been impacted by hazardous substances and other natural or man-made emergencies. The USDA may be contacted through the U.S. Forest Service emergency staff officers who are the designated members of the RRT.

USDA maintains trusteeship of national forest, wilderness areas, and wildlife within USDA- controlled forests, archaeological sites, range and farm lands, fisheries, and lands enrolled in the Wetlands Reserve Program. Additionally, the USDA plays a key role in the closing and re-opening of fisheries before, during, and after clean-up operations.

Department of Energy (DOE)

The Secretary of Energy has trusteeship over natural resources under its jurisdiction, custody, or control. DOE's land-holdings include national research and development laboratories, facilities, and offices.

The DOE Office of Petroleum Reserves (OPR) oversees the Strategic Petroleum Reserve (SPR), the world's largest supply of emergency crude oil, which was established primarily to reduce the impact of disruptions in supplies of petroleum products and to carry out obligations of the United States under the international energy program. The federally-owned oil stocks are stored in huge underground salt caverns at four sites along the coastline of the Gulf of Mexico in Texas and Louisiana. There are no storage SPR facilities located within the SECDELBAY_ACP planning area.

U.S. Department of Transportation (DOT)

DOT provides response expertise pertaining to transportation of oil or hazardous materials by all modes of transportation. Through the Pipeline and Hazardous Materials Safety Administration (PHMSA), DOT-PHMSA offers expertise in the requirements for packaging, handling, and transporting regulated hazardous materials.

Department of Defense (DoD)

- **U.S. Army Corps of Engineers (USACE)**
  The Secretary of the DoD has trusteeship over the natural resources on all lands owned by DoD or the Army (including lands and facilities managed by the USACE, Navy, Air Force, and Defense Logistics Agency). These lands include military bases and training facilities, research and development facilities, and munitions plants. USACE has trusteeship over natural resources under its jurisdiction, custody, or control. USACE landholdings include national research and development laboratories, facilities, and offices. Additionally, the USACE provide information on river levels within

this ACP planning area. The USACE does not currently provide river level data for the SecDelBay planning area.

- **U.S. Navy Supervisor of Salvage (SUPSALV)**
  SUPSALV has an extensive salvage/search and recovery equipment inventory, and the requisite knowledge and expertise to support these operations including specialized salvage, firefighting, and petroleum, oil, and lubricants offloading capability even in open sea response incidents. SUPSALV can also provide equipment for training exercises in support of national and regional contingency planning objectives. The FOSC may request assistance directly from SUPSALV. Formal requests are routed through the Chief of Naval Operations.

- **National Guard Civil Support Teams (CSTs)**
  CST were created in 1999 to respond to terrorist incidents involving WMD, as well as other disasters and catastrophic events, both natural and man-made. There are 57 CSTs located throughout the United States, with at least one in each state and territory. The mission of a CST is to support civil authorities at a domestic CBRNE (Chemical, Biological, Radiological, Nuclear, and high-yield Explosives) incident site with responsibilities such as identification and assessment of hazards, advising civil authorities, and facilitating the arrival of follow-on military forces during emergencies and incidents.

  CSTs normally operate as a State asset, under the command and control of the State Governor, but upon deployment, the unit provides direct support to the IC. CSTs support local emergency responders (Fire, Police, and EMS), as well as State and Federal agencies such as the DOE, FBI, EPA and FEMA.

Federal Investigative Services

Federal Agency Legal and Investigative Support

U.S. Department of Justice (DOJ)

DOJ can provide expert legal advice on complicated legal questions arising from discharges or releases and federal agency responses. The DOJ represents the federal government, including its agencies, in litigation relating to discharges.

Federal Bureau of Investigation (FBI)

The FBI, under the DOJ, is the lead federal agency for responding to threats from weapons of mass destruction (WMD). The Bureau investigates and collects intelligence on WMD-related threats and incidents to prevent attacks and respond to them when they occur. WMD Directorate (WMDD) is part of the FBI's National Security Branch. The WMDD leads the FBI's efforts to mitigate threats from chemical, biological, radiological, nuclear, or explosive weapons. The WMDD provides leadership and expertise to domestic and foreign law enforcement, academia, and industry partners on WMD issues. The FBI approaches these issues through four major areas: preparedness, countermeasures, investigations/operations, and intelligence.

U.S. EPA Criminal Investigations Division (EPA CID)

The EPA CID investigates allegations of criminal wrongdoing prohibited by various environmental statutes. Such investigations involve, but are not limited to, the illegal disposal of hazardous waste; the export of hazardous waste without the permission of the receiving country; the illegal discharge of pollutants to a water of the United States; the removal and disposal of regulated asbestos containing materials in a manner inconsistent with the law and regulations; the illegal importation of certain restricted or regulated chemicals into the United States; tampering with a drinking water supply; mail fraud, wire fraud, conspiracy and money laundering relating to environmental criminal activities. CID Special Agents are sworn federal law enforcement officers with statutory authority to conduct investigations, to make arrests for any federal crime, and to execute and serve any warrant.

U.S. Coast Guard Legal

The Fifth Coast Guard District has a legal staff that is available to provide support to the USCG FOSC. Additionally, and as needed, USCG Atlantic Area and headquarters can provide legal assistance to the USCG FOSC.

U.S. Coast Guard Investigative Service (CGIS)

CGIS Agents are available to investigate criminal violations of environmental laws enforced by the Coast Guard. CGIS should be notified and consulted regarding all cases that may be referred to the Department of Justice for criminal prosecution. CGIS Agents are trained criminal investigators who are familiar with the legal issues associated with prosecution of a criminal case. Additionally, CGIS Agents regularly work with agents of other Federal, State, and local law enforcement agencies and frequently become aware of violations of environmental laws and ongoing criminal investigations through these sources.

Unless expressly directed by the Chief of CGIS or higher authority, CGIS will not conduct an environmental crime investigation in a COTP zone without first notifying and, thereafter, coordinating with the COTP. Likewise, the COTP should avoid committing the Coast Guard to participate in criminal investigations, either solely or in coordination with other enforcement agencies, without first consulting the District Commander who will ensure appropriate coordination with CGIS. In the event exigent circumstances require the initiation of a criminal investigation before such notification or consultation can occur, the required communication must occur as soon as practical thereafter.

National Transportation Safety Board (NTSB)

In accordance with the USCG/NTSB MOU and 46 C.F.R. 4.40-15(b), the NTSB shall conduct the investigation of certain major marine and public/nonpublic vessel casualties. Except for the preliminary investigation, a separate Coast Guard casualty investigation will not be conducted, nor will parties in interest be designated by the Coast Guard. Although these investigations are conducted by the NTSB in accordance with their procedures, the Coast Guard will participate fully as a party.

Annex EE

Non-Government Agencies Who Can Support the FOSC

Nongovernmental Organizations, Academia, and Other Technical Support

Science and Technology Advisors (S&T Advisors)

S&T Advisors consist primarily of academia and represent specialized capabilities to provide knowledge, based on science and other technical experience, to supplement and strengthen that of the Incident Management Team (IMT).

The advisory capability may consist of individuals or institutions and may be identified during the preparedness phase or by incident-specific needs. The relationship may be as informal as a list of

names and contact information in a directory, or a more formal pre-spill relationship defined through letter of agreement.

- Delaware River Basin Commission
- The Partnership for the Delaware Estuary (PDE Science Directory)

Seafood Liaison Specialist (SLS)

During a response, the seafood/fishing industry is directly impacted by agency decisions that result in fishery closures and subsequent seafood safety testing. Having the capability to engage with all stakeholder groups helps cultivate a broad capability to understand, monitor, characterize, and model hazards that can inform all levels of preparedness and response decisions.

The SLS is a technical advisor that provides a way to collaborate and share information between the Incident Management Team (IMT), the seafood harvesting community, e.g., fishers, seafood restaurants, the agencies responsible for managing fishery closures and seafood safety, and others in the seafood industry. Guidance for the SLS position is located in Annex 42 of the RRT-3 RCP.

- FDA – NJ and Delaware - Shell Fish Branch #2, Office of State Cooperative program, Voorhees, NJ (856)290-4019
- National Marine Fisheries (NOAA)

Volunteers

In times of crisis or trouble, many citizens feel compelled to help or lend their assistance and expertise to the response effort. This help can be welcome if the demands of an incident exceed the available resources or if a particular set of skills are in short supply. Volunteers can support response efforts in any number of ways such as conducting beach surveillance, providing logistical support, or assisting in the treatment of impacted wildlife. The decision to employ volunteers will take into account the benefits that might be gained weighed against safety and liability realities. The UC, in the early stages of the event, will make the decision whether volunteers will be employed and in which capacities they can serve. For more details about the use of volunteers, please refer to

Annex 6a – and Volunteer section of this ACP, and the National Response Team's Use of Volunteers Guidelines for Oil Spills and the Volunteer Plan, (NRT - PLAN LINK).

Certified Marine Chemist (CMC)

The United States Coast Guard and the Occupational Safety and Health Administration (OSHA) require that a certificate issued by a Marine Chemist be obtained before hot work or fire producing operations can be carried out in certain spaces aboard a marine vessel.

In complying with both the U.S. Coast Guard and OSHA regulations, the CMC applies the requirements contained in National Fire Protection Association Standard 306. NFPA 306, Control of Gas Hazards on Vessels, describes conditions that must exist aboard a marine vessel. A survey by the Marine Chemist ensures that these conditions are satisfied. In addition, a CMC is able to perform similar evaluations on other than marine vessels where an unsafe environment exists for workers, or hot work is contemplated on a system that might contain residues of a flammable or combustible product or material. See National Fire Protection Association (NFPA) Certified Marine Chemists for a list of certified Marine Chemists.

Water Sampling Technical Specialist

The Water Sampling Technical Specialist is an advisor responsible for helping to create the water sampling and analysis plans, including the Initial Incident Characterization Sampling and Analysis Plan, and any needed updates throughout the response based on the sampling results. The Water Sampling Technical Specialist is responsible for monitoring the progress of sample analysis at the designated laboratory and making arrangements for receipt of data. A detailed plan for Water Sampling during an oil spill or hazardous substance release can be found in Annex 5b.

Community Air Monitoring (CAM) Coordinator

The CAM Coordinator leads CAM efforts during emergencies in order to measure, identify, and quantify airborne contaminants. The CAM uses these results as a baseline to facilitate fact-based decisions made by officials, ultimately safeguarding human health and the environment. The EPA has been pre-designated the CAM Coordinator in the Sector Delaware Bay AOR.

Threatened and Endangered Species

Oiled Wildlife Annex

Oiled Wildlife Response Quick Reference Guide

Oiled Wildlife Response Organization Contact Information		
*Note: These numbers should only be used in regards to oil spill responses or drills/exercises		
Tri-State Bird Rescue & Research, Inc. (Newark, DE) 1-800-261-0980	**International Bird Rescue** (Los Angeles & San Francisco, California) 1-888-447-1743	**Focus Wildlife** (Anacortes, Washington) 1-800-578-3048

Initial Wildlife Response Steps to Take Within the First 24 Hours of an Oil Spill Response

*Note: These steps should be taken even if no wildlife impacts are readily apparent.

*See page 22 for a more extensive list of initial steps.

1. Notify appropriate wildlife trustees that a spill has occurred.
    a. See page 23 for list of applicable trustees.
2. Alert an Oiled Wildlife Response Organization (OWRO) to notify them that a spill has occurred.
    a. This should be done even if a Wildlife Branch has not been established and the response is not ready to contract an OWRO yet. Early notification allows for more efficient deployment if an OWRO is needed as the response develops.
    b. **Identify who in the response will be authorized to sign a contract if activation of an OWRO is needed.** (See page 23 for more details)
3. The Environmental Unit should initiate a wildlife impact assessment.
    a. Identify who will carry out the assessment – possibilities include an OWRO, SCAT team, wildlife trustee agencies, etc.
4. Decide if hazing and deterrence is needed to prevent wildlife from becoming oiled.
    a. Identify who will carry out the hazing and deterrence and ensure they have the proper authorization (see page 28 for more details).

What Not to Do

1. Do not allow any untrained/unpermitted personnel to capture or disturb wildlife.
2. Do not attempt to decontaminate any oiled wildlife.
3. Do not hire a group to care for oiled wildlife without checking that they meet the requirements described in page 11 of this annex.

Wildlife Branch Operations 27
Wildlife Branch Demobilization 34

Introduction

This Oiled Wildlife Response Annex was developed to provide information outlining the responsibilities and actions of the Wildlife Branch during an oil spill response within Sector Delaware Bay. The information in this section is pertinent even for oil spill situations where wildlife impacts are not readily apparent; oil releases almost always have some effect on wildlife, even if oiled animals are not immediately visible at the spill site.

This contingency plan covers the protocols and guidelines for initiating and sustaining an oiled wildlife response. This contingency plan may be used as a reference by the contracted Oiled Wildlife Response Organization (OWRO); however, it does not replace the years of experience necessary to successfully manage and carry out an oiled wildlife response. This contingency plan will meet the following objectives in order to facilitate effective and efficient oiled wildlife responses within the Area of Operation (AOR) of Sector Delaware Bay:

- Ensure human health & safety in all aspects of the oiled wildlife response.
- Define what qualifications an OWRO needs to effectively manage an oiled wildlife response.
- Identify species and habitats at risk of harm from oil spills in the AOR of Sector Delaware Bay.
- Identify facility requirements for oiled wildlife response and identify specific sites that meet those requirements in the AOR.

- Identify roles and responsibilities of individuals in the Wildlife Branch and Environmental Unit according to the Incident Command System.
- Outline initial response actions to ensure a timely and effective wildlife response is initiated, including appropriate notifications to regulatory agencies and key response personnel.
- Describe documentation procedures.
- Describe operations procedures and requirements.
- Describe the process of demobilizing the Wildlife Branch.

This Oiled Wildlife Response Annex functions as a contingency plan as part of the Sector Delaware Bay Area Contingency Plan (ACP); in the event of an oil spill an incident-specific Wildlife Management Plan (WMP) should be established according to the specific needs of the response. The WMP should be written by the Environmental Unit of the Planning Section in conjunction with the Wildlife Branch in the Operations Section.

Human Health and Safety

During oiled wildlife response operations, responder safety is paramount. A thorough site survey and hazard assessment should be conducted before the commencement of any operations and an incident-specific Site Safety Plan should be developed (See Section 2200 of the Sector Delaware Bay ACP). This plan will include a physical description and map of the site and identify hazards, key staff, security procedures, emergency contacts, and required personal protective equipment (PPE).

PPE

All workers must be trained on the proper use and limitations of required PPE prior to using the equipment. Working with oiled wildlife requires the use of PPE specific to the contaminant, such as coveralls, nitrile gloves, and safety glasses. In addition to hazards from oil, other physical hazards may be associated with wildlife rescue activities. For example, additional PPE may be required to protect against bites and scratches, such as leather gloves.

Zoonoses

Zoonoses are diseases that are transmissible between animals and humans, posing risks to the health and safety of humans as well as wildlife patients in care. Examples include rabies, toxoplasmosis, and coccidia. Responders with compromised immune systems, pregnant responders, and elderly responders are more susceptible to these diseases. Steps necessary to mitigate the risks include wearing proper PPE and washing hands thoroughly after handling animals and performing animal husbandry. **Wildlife responders who may come into contact with mammals must have received the pre-exposure rabies vaccine**.

A wildlife veterinarian should be consulted when forming the incident Site Safety Plan and the Wildlife Management Plan in order to appropriately assess the risk of zoonotic diseases for each response. The veterinarian can help identify appropriate PPE as well as quarantine protocols for the animals in care. Special considerations may need to be taken in times of an outbreak of a wildlife disease, such as Highly Pathogenic Avian Influenza.

Job Health and Safety Risks

The following tables identify health and safety risks for the jobs that wildlife staff could perform during an oiled wildlife response. See the Oiled Wildlife Response Organization Qualifications section for additional information on safety training.

Table 1. Job-specific risks for wildlife staff during an oiled wildlife response.

	ICP	ld Operations								Primary Care Center

Species and Habitats at Risk during Oil Spills

Species

Many wildlife species in Sector Delaware Bay's AOR are at particular risk of harm from oil spills, especially considering the area's position in a major bird migration flyway. This section focuses on species at risk according to input from local wildlife trustees and their status on the federal and/or state Threatened & Endangered (T&E) lists.

Key species are listed in the following table. For a full list of species at risk, including their listing status, breeding season, and critical habitat within Sector Delaware Bay, click the following link (this list is subject to change):

https://acrobat.adobe.com/id/urn:aaid:sc:VA6C2:a2e31634-60c2-4e7c-98f2-5475cda9d564

Table 3. Key species at risk in the Sector Delaware Bay AOR.

Species	Status
Mammals & Marine Mammals	
Indiana Bat (*Myotis sodalis*)	Endangered NJ, PA
Little Brown Bat (*Myotis Lucifugus*)	Endangered
Northern Long-eared Bat (*Myotis septentrionalis*)	Endangered
Harbor Seal (*Phoca vitulina*)	Marine Mammal Protection Act
Gray Seal (*Halichoerus grypus*)	Marine Mammal Protection Act
Birds	
Black Rail (*Laterallus jamaicensis*)	Endangered in NJ
Piping Plover (*Charadrius melodus*)	Threatened
Roseate Tern (*Sterna dougallii dougallii*)	Endangered (Northeast population)
Red Knot (*Calidris canutus rufa*)	Threatened & Endangered DE, NJ, PA
Reptiles	
Bog Turtle (*Glyptemys muhlenbergii*)	Threatened
Eastern Massasauga (*Sistrurus catenatus*)	Threatened
Green Sea Turtle (*Chelonia mydas*)	Endangered
Hawksbill Sea Turtle (*Eretmochelys Imbricata*)	Endangered
Kemp's Ridley Sea Turtle (*Lepidochelys kempii*)	Endangered
Leatherback Sea Turtle (*Dermochelys coriacea*)	Endangered
Loggerhead Sea Turtle (*Caretta caretta*)	Endangered
Diadromous Fish	
Atlantic Sturgeon (*Acipenser oxyrinchus oxyrinchus*)	Species of concern
Shortnose Sturgeon (*Acipenser brevirostrum*)	Endangered
Crustacean	
Horseshoe Crab (*Limulus polyphemus*)	Not listed
Insect	
Bethany Firefly (*Photuris bethaniensis*)	Endangered DE

Further information on species at risk in the Sector Delaware Bay area can be found here:

- https://dnrec.delaware.gov/fish-wildlife/conservation/endangered-species/
- https://www.pgc.pa.gov/Wildlife/EndangeredandThreatened/Pages/default.aspx
- https://dep.nj.gov/njfw/wildlife/endangered-threatened-and-special-concern-species/#endangered-and-threatened

Habitats

A habitat is considered at risk of harm from oil spills if it is particularly sensitive to damage, hosts a wide variety of organisms, or acts as key habitat for a T&E species. The following locations are considered at risk and should be treated with special consideration to prevent damage during oil spills.

Map Key

- National Wildlife Refuge/National Fish Hatchery
- Coastal Barriers
- Water Bodies

Follow this link for an interactive version of the map above, including names of the coastal barriers:

https://ipac.ecosphere.fws.gov/location/44JPSF4KYRH55NHHAPRQCJXLRE/resources#coastal-barriers

Oiled Wildlife Response Organization Qualifications

Oiled wildlife response requires specific skills, equipment, certifications, and experience in order to conduct operations safely and effectively. While local wildlife rehabilitators may be an excellent resource during an oil spill because of their expertise with wildlife in the area, most rehabilitators do not specialize in oiled wildlife response. In order to ensure that the oiled wildlife response goes as smoothly as possible, the Oiled Wildlife Response Organization (OWRO) contracted to manage the response should meet the criteria discussed in this section.

Permits

State and federal permits may be required for various aspects of the oiled wildlife response. In order to legally carry out the required response activities, the OWRO must either preemptively hold the necessary permits or be granted the permits by the appropriate authority at the time of the spill. See the following tables for specific permit information.

Table 4. Permit information for oil spill response activities: **Migratory birds.**

ACTION	PERMIT NAME	AUTHORIZING LAW OR REGULATION	Details
Hazing/Deterrence	Hazing Permit Incidental Take Permit	Endangered Species Act, Section 10(a)(1)(B)	Special permission is required to "take" endangered species
	Hazing Permit Eagle Take-Associated with, but not the Purpose of, an Activity (Incidental Take)	Bald and Golden Eagle Protection Act, 50 CFR 22.80	Bald and golden eagles have special protections under this act
	Local wildlife trustees should be consulted prior to hazing to ensure the proper protocols, trainings, and certifications are in place.

Personnel Training and Certifications

In order to work with wildlife that is contaminated with petroleum products, personnel should have the appropriate level of hazardous material training, as defined by 29 CFR 1910.120 and as identified by the incident Safety Officer.

- Personnel working directly with oiled animals, in the field or at a care center, should have a **24-hour Hazardous Waste Operations and Emergency Response (HAZWOPER)** certification, with an annual **8-hour refresher HAZWOPER** course.
- Personnel working in a support or administrative role (i.e. not in contact with any oiled animals) should have a **Hazardous Communications (HazCom)** certification.
- Personnel working remotely do not need a hazardous material certification.

In addition to hazardous material training, personnel should have training and experience relevant to the animal care they will be doing. This includes experience with animal field capture, animal handling, administering medical treatments, performing exams, and decontaminating animals, among many others. See Table 8 for specific trainings that wildlife personnel should have completed prior to the response.

OWRO staff and volunteers who have not had sufficient training prior to responding to an oil spill may receive on-site just-in-time training conducted by an individual with prior response experience, in coordination with the incident Safety Officer; alternatively, these individuals may be assigned less hazardous duties appropriate to their current level of training.

Table 8. Trainings and certifications required or recommended for wildlife personnel.

Training / **Personnel**	HAZWOPER	ICS 100-300	Aircraft Safety	Boating Safety	Firearm Safety	First Aid/CPR	Basic Rehabilitation Skills	Animal Washing	Supervisory and Crisis Management
USFWS Response	R	R	R	R	R	R	-	-	-
Rehab Management	R	R	-	-	-	H	H	H	H
Initial Assessment	R	-	H	H	-	H	-	-	-
Bird Deterrent	R	-	-	H	H	H	-	-	-
Field Workers	R	-	-	H	-	H	H	-	-
Facility Workers	R	-	-	-	-	-	H	H	-

R = Required Training, if performing the activity
H = Highly recommended for establishing best practices, if performing the activity

Veterinary Requirements

Oiled wildlife response requires the oversight of a licensed wildlife veterinarian because of the host of health issues caused by petroleum exposure; furthermore, the states of Delaware, New Jersey, and Pennsylvania require permitted wildlife rehabilitators to work with a veterinarian. A veterinarian must have a current Drug Enforcement Administration license in order to use controlled substances, which are often critical for adequate veterinary care of oiled wildlife. This includes the use of euthanasia solution, which must be readily available during oiled wildlife responses in order to perform humane euthanasia at the discretion of a veterinarian.

Wildlife disease management is also a concern during oiled wildlife responses; involving a wildlife veterinarian in the response can be a critical factor in establishing adequate disease monitoring, prevention, and containment protocols. State wildlife veterinarians may also need to be involved in the response if there is an active outbreak of a disease of concern (for example, Highly Pathogenic Avian Influenza).

Volunteers

Unpaid volunteers may be involved in an oiled wildlife response. These individuals are subject to the same training requirements listed above. Just-in-time or convergent volunteers may be

utilized, but they must receive adequate training at the time of the response in order to meet these requirements. The OWRO should also have adequate liability insurance that includes coverage for volunteers.

Other Requirements

The contracted OWRO should have adequate knowledge and experience with the various aspects of an oiled wildlife response, including the following: ICS positions, facility requirements, documentation and communication within the ICS, identification of oiled wildlife in the field, field capture of oiled wildlife, transporting oiled wildlife, and communicating appropriately with the media, among others.

Facility Requirements and Identification

Oiled wildlife responses require facilities with specific characteristics in order to effectively stabilize, decontaminate, and rehabilitate contaminated wildlife. This section will discuss the requirements for two types of oiled wildlife facility, a Stabilization Facility and a Primary Care Center, and will list some facilities that meet these requirements in the Sector Delaware Bay AOR.

Stabilization Facility

A Stabilization Facility may not be needed in every oil spill response. If a Primary Care Center cannot be located within a 2-hour drive of the spill site or if the animals recovered from the spill site are especially debilitated, an on-site or nearby Stabilization Facility will be established. A Stabilization Facility could be in the form of a brick-and-mortar building, a mobile trailer, or a field tent, depending on the incident circumstances (note – the OWRO may need assistance from the Logistics Section to source a Stabilization Facility, especially if a trailer or tent is desired). Stabilization Facilities require the following characteristics:

- Private shelter with protection from the elements and restricted access from the public
- Temperature control
- Ventilation
- Electricity
- Adequate space for patients in their transport carriers
- Adequate space for a treatment area

The goal of a Stabilization Facility is to provide supportive care (i.e. emergency treatments, fluid therapy, normalizing body temperature) for patients who are extremely debilitated and/or will be traveling a long distance to the Primary Care Center. This supportive care can drastically increase a patient's chance of survival, as the initial 24-48 hours of care are most critical for an oiled animal. The Stabilization Facility should be staffed by OWRO personnel or personnel who have been trained by the OWRO to stabilize oiled wildlife.

Oiled Wildlife Response Facility/Primary Care Center

The ideal location for the Primary Care Center is rarely at the spill site; under certain circumstances the center can be located several hours away from the spill site. A facility's ability

to safely provide medical and rehabilitative care is more important than its proximity to the spill site. In remote areas or locations where an adequate facility cannot be identified within a 2-hour drive of the spill site, temporary stabilization sites may be required to ensure that appropriate emergency care is provided to wildlife prior to transport (see above).

Primary Care Center requirements can vary significantly, depending on the following:

- Overall scale of the spill and potential wildlife impact
- Species and age of wildlife affected
- Geographic location
- Season/weather
- Type of contaminant(s)

Facility requirements can vary significantly depending on the circumstances of the incident; therefore, a permanent facility (for example, a local wildlife rehabilitator's facility) is not always advisable and may actually be an impediment in providing the appropriate facility design for the situation.

A suitable Primary Care Center will possess the following characteristics:

- A large, open floor space (**~3,000ft^2**)
    - A large, open floor space allows responders to easily reconfigure equipment as the needs of a response change. Plastic sheeting (4 mil) is secured to the floor of the facility with painter's tape in areas where animals will be housed to protect the floor and for ease of clean up during demobilization.
- Adequate HVAC system
    - The HVAC system must be able to maintain the temperature of the open floor space between **70°F and 80°F**. To protect responders and patients from toxic contaminant fumes, an HVAC system capable of up to 10 air exchanges per hour is ideal.
- Reliable water supply
    - A response can use up to **7,000 gallons per day**. Water may be used for drinking water for responders, care for patients, or decontamination. Water used for decontamination will be contained within a containment berm and pumped into oily waste water containers.
- Reliable power
    - Oiled wildlife response can require many pieces of equipment including refrigerators/freezers, medical equipment, power tools, pool pumps, and washers/driers. The facility needs to have an adequate number of outlets and the ability to handle the power draw of running much or all of the need equipment simultaneously.
- Adequate parking
    - Oiled wildlife response is resource intensive and one of the most important resources is people. Personnel needs fluctuate as a response progresses and can be significant. **Parking for up to 50 responders is desirable.**

- Security
    - Security is necessary to restrict/control access to the facility and prevent unauthorized individuals from accessing response operations. This protects unauthorized visitors from hazards associated with spill response, protects responders/patients from unauthorized visitors, and ensures that your property is protected.

Pre-identifying real estate that may be suitable for oiled wildlife response within the AOR will help expedite an oiled wildlife response. Each location should be thoroughly surveyed, ideally by an OWRO, using a *Facilities Checklist* such as the following: https://acrobat.adobe.com/id/urn:aaid:sc:VA6C2:f638e12f-851c-4678-b232-f3202768c835.

As of February 2024, the following facilities have been identified as possible Stabilization Facilities and/or Primary Care Centers:

- **Tri-State Bird Rescue & Research, Inc.** 170 Possum Hollow Rd, Newark DE 19711. (302) 737-9543.
    - Suitable for small-large scale responses involving birds, reptiles, amphibians, and terrestrial mammals.
- **Prime Hook National Wildlife Refuge.** 11978 Turkle Pond Rd, Milton DE 19968. (302) 684-8419.
    - Suitable for small-medium scale responses involving birds, reptiles, amphibians, and terrestrial mammals.
- **Marine Education, Research, and Rehabilitation (MERR) Institute**. 801 Pilottown Rd, Lewes DE 19958. (302) 228-5029.
    - Suitable for small scale responses involving marine mammals and sea turtles. Possesses some limited capabilities for birds, reptiles, and amphibians.

Pre-Release Conditioning

Occasionally the Primary Care Center will not be suitable for long-term care for decontaminated patients that need intensive pre-release conditioning. See the International Wildlife Rehabilitation Council/National Wildlife Rehabilitators Association *Standards for Wildlife Rehabilitation* for housing, rehabilitation, and conditioning standards for each taxa of wildlife. These standards are particularly important to follow to ensure that aviaries and pools are adequate to condition seabirds for release.

Local rehabilitation facilities within the Sector Delaware Bay AOR are listed below with their taxa and short or long-term housing capabilities.

- Tri-State Bird Rescue & Research, Newark, DE
    - Avian[2], Mammal[2], Reptiles[2], Amphibians[2]
- National Aquarium, Baltimore, MD
    - Marine Mammals[1], Sea Turtles[2]
- National Aquarium Animal Rescue Stranding Response Center, Ocean City, MD

    - Marine Mammals[1]
- Marine Education Research and Rehabilitation (MERR) Institute, Lewes, DE
    - Marine Mammals[1]
- Marine Mammal Stranding Center, Brigantine, NJ
    - Marine Mammals[2]
- Mercer County Wildlife Center, Lambertville, NJ
    - Avian, Mammals[2]
- Schuylkill Wildlife Center, Philadelphia, PA
    - Avian[2], Mammals (no rabies vector species)[2], Reptiles[2], Amphibians[2]
- Raptor Trust, Millington, NJ
    - Avian[2]

[1]Short-term, [2]Both short-term and long-term

Incident Command Structure

Wildlife Response

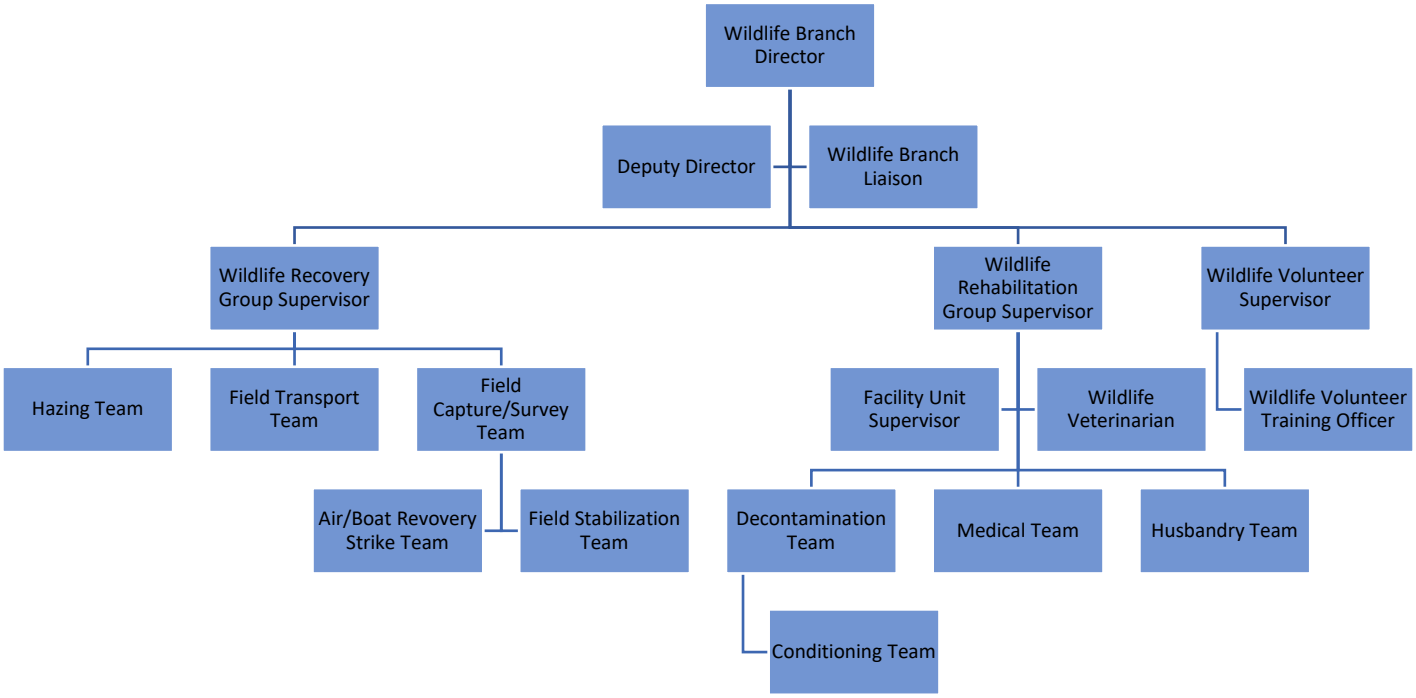
In the event of a spill or threat of a spill occurring within Sector Delaware Bay's AOR impacting or potentially impacting the environment, a Unified Command shall be activated. The Incident Management Team will be responsible for initiating an oiled wildlife response. Wildlife response actions will comply with NIMS-ICS standards and follow a Wildlife Branch organization structure.

Wildlife Branch staff will coordinate with personnel from the Operations Section, Logistics Section, Planning Section (Environmental Unit), and Finance Section as needed to advocate for and represent Wildlife Branch needs. Resource requests will be submitted through the Logistics Section using ICS 213RR forms. All financial activity will be documented and submitted through the proper channel; this may be through the Finance Section or directly through the RP depending on the structure of the response and how the OWRO was contracted in to the response.

The Wildlife Branch will be part of the Operations Section. Depending on the magnitude of the wildlife response, additional command staff may be required within the Wildlife Branch. Command staff may include:

- Assistant Safety Officer for Wildlife
- Assistant Liaison Officer for Wildlife
- Public Information Officer for wildlife-related issues

Below is an example organization chart for the Wildlife Branch.



Initial Response Actions

Response Priorities

Response activities are prioritized to ensure an effective wildlife response. The following activities shall be initiated within the first 24-48 hours of an incident:

- Conduct notifications to wildlife trustees.
- Mobilize an OWRO.
    - Once mobilized, an OWRO can handle most, if not all, of the rest of these initial response priorities.
- Initiate a wildlife impact assessment.
- Mobilize and deploy wildlife equipment, supplies, and additional OWRO personnel.

- Develop and implement an incident and species-specific Wildlife Deterrents (Hazing) Plan.
- Develop an incident-specific Wildlife Management Plan.
- Ensure that required federal and state permits are in place or that applications for appropriate permits are submitted.
- Establish a "1-800" oiled wildlife reporting hotline.
- Identify regional resources needed for a wildlife response and initiate establishment of required oiled wildlife care facilities.
- Conduct reconnaissance and recover carcasses to reduce secondary contamination of wildlife.

Notifications

In the event of an oil spill (or other relevant contaminant) that has impacted wildlife, or has the potential to impact wildlife, a representative from Sector Delaware Bay should ensure notification is provided to the United States Fish and Wildlife Service and any additional local wildlife trustees. These regulatory agencies have authority over wildlife and other resources at risk. Local wildlife trustees in the AOR of Sector Delaware Bay include:

- Delaware Department of Natural Resources and Environmental Control
- New Jersey Department of Environmental Protection
- Pennsylvania Game Commission (birds and mammals)
- Pennsylvania Fish and Boat Commission (reptiles, amphibians, fish)
- Administrators for state or federally-managed natural areas affected by the spill
- Department of Interior Regional Environmental Officer
    - John Nelson (PA, DE) – Philadelphia Regional Office, (215) 597-5378
    - Andrew Raddant (NJ) – Boston Regional Office, (617) 223-8565
- US Fish & Wildlife Service Regional Spill Response Coordinator
    - Margret Byrne, USFWS Northeast Region 5, (413) 253-8593

Oiled Wildlife Response Organization Activation

There are a few ways to contract an OWRO during an oil spill response.

- The Responsible Party (RP) may contract directly with the OWRO.
    - This is typically the fastest and most efficient method.
- If the RP is not determined and the USCG is opening the Oil Spill Liability Trust Fund, the OWRO will typically be sub-contracted through an Oil Spill Response Organization (OSRO).
    - If the OWRO holds a Basic Ordering Agreement (BOA) with the USCG, the OWRO can be contracted directly through the USCG.
- If an agency (e.g. USFWS, EPA) has requested that an OWRO be activated, then the funding will need to be determined on a case-by-case basis.

To activate Tri-State Bird Rescue & Research's (TSBRR) Oiled Wildlife Response Team, please call the following 24-hour emergency contact hotline: **(800) 261-0980.**

Use this number ONLY to notify TSBRR of an oil spill or oil spill drill/exercise.

For non-emergency situations please contact:

Main Office: **(302) 737-9543 x 121** Email: **oilprograms@tristatebird.org**

The caller shall be prepared to provide the OWRO with appropriate contact information and a synopsis of the incident. This includes the type of contaminant and amount spilled, type and number of animals affected, and type of habitat affected.

The OWRO along with the Environmental Unit and Operations Section Chief will determine the best path forward for wildlife response operations.

Oiled Wildlife Reporting Hotline

An appropriate interface with the public shall be established. In most cases this will be in the form of a Wildlife Observation Reporting Hotline which will collect information on impacted wildlife sightings from the public and receive and record sightings from response personnel.

The Hotline shall be staffed with appropriate personnel representing USCG Sector Delaware Bay. The Wildlife Branch will provide the Hotline personnel with approved messaging about the wildlife response to convey to callers from the public. Messaging will instruct callers not to attempt capture of the animal due to health and safety concerns for both the individual and the animal. Observation data from callers will be recorded and communicated to the Situation Unit and Wildlife Branch for assessment and subsequent action.

The Wildlife Observation Reporting Hotline number and messaging shall be included in daily work assignments (***ICS-204***) ensuring that observations made by response personnel are reported, documented and communicated to the Wildlife Branch in a similar fashion.

Additionally, appropriate messaging will be developed and provided to the Joint Information Center or Public Information Officer to release as media notices.

Documentation

Data Collection and Chain of Custody Records

All wildlife data collected will be important for documenting ongoing response efforts and meeting evidentiary requirements. These data may also be incorporated into Natural Resource Damage Assessment activities. During the initial phase of a wildlife response the Unified Command, wildlife trustees, and the OWRO shall agree on all the documentation procedures before commencing wildlife recovery efforts. All responders shall adhere to the procedures throughout the response. All team members shall be briefed on appropriate methods to record and store the data they are required to collect.

Wildlife Field Observations

The wildlife field teams will record animal sightings (both impacted and non-impacted) and any pertinent information about field activities as they relate to wildlife. Wildlife field observations can be recorded on paper (see Figure 1 for a sample field survey) or digitally using the United

States Fish & Wildlife Service (USFWS) Wildlife Response Survey through Survey 123. All forms must include the following information:

- Field team members
- Contact information for field team
- Location where the field team worked (GPS coordinates, detailed landmarks)
- Method of survey (e.g. on foot, boat, car, etc.)
- Time and date
- Incident name

Photographic documentation generated during field operations should be submitted to the Documentation Unit daily. When possible, written documentation should accompany photographs (location, description of why photograph was taken, etc.).

Chain of Custody Forms

At the onset of any oiled wildlife response effort local the USFWS Field Spill Response Coordinator (FSRC) should be consulted for incident-specific Chain of Custody procedures. In the absence of immediate input, the following general procedure should be practiced with due diligence.

Once an impacted animal is collected, the recovery team shall begin a chain of custody form. This form should include the following information:

- Field team members
- Contact information
- Location of collection (preferable GPS coordinates)
- Species (if known)
- Time and date animal was collected
- Incident name
- Indication of whether the animal is dead or alive
- Indication of whether the animal is oiled or not

This form must stay with the individual animal at all times. Forms should be placed in a plastic Ziploc® bag and attached to the animal's transport carrier. If possession changes hands, then the form must be signed (signature, date and time) by the person who is relinquishing custody. The person receiving custody must also sign the form (signature, date and time) and his / her contact information must be added to the form. Both parties shall retain a copy of the form. Carcasses should only be given to people with the authority to have possession.

Custody forms for live animals should be filed systematically once the animal arrives at the Wildlife Response Facility. All forms for carcasses should be attached to the carcass, unless asked to do otherwise by the law enforcement agent in charge of evidence. Depending on the species, status, and retrieval location there may be multiple agencies with law enforcement representation. Incident-specific protocols may be amended based on jurisdiction of agencies.

Individual Animal Logs

All live animals recovered by the field teams will be assigned a case number unique to the incident and an individual animal case record will be started for each animal upon arrival at the Wildlife Response Facility. A case number for each animal should be generated from a running tally and recorded on the animal's log. The case number will be the animal's identification while in the rehabilitation facility. The animal's log will follow the progress of the individual from the initial intake through release. Significant information will be recorded about the animal's health and rehabilitation status; anyone writing on the form is required to sign and date their additions.

Collected carcasses will also receive a unique number generated from a morgue log and will be recorded on the chain of custody form. Any additional information that might be required can be added to the chain of custody form. All individuals adding information to the chain of custody form must sign and date their additions.

Animal Evidence Samples

Evidence samples shall be collected from all animals (live and carcasses) arriving at the facility. Law enforcement representatives with appropriate jurisdiction should be consulted at the onset of wildlife efforts on what samples to collect, who can take the samples, how to label the samples and how to store the samples.

Samples at a minimum should include the following information:

- Date and time of collection
- Sample type
- Incident name
- Species
- Case number
- Collector's name

During the admission process photographs will be taken of each animal or carcass, including a tag with the date, time, species, case number and temporary band ID number, and incident name in large, black letters. The original data cards containing the photographs should be given directly to law enforcement or securely stored when not in use. Additionally, data on any card designated for evidence should never be shared or downloaded to another device.

Law enforcement must also approve carcass storage methods. Incident specific protocols may be amended based on jurisdiction of agencies. For more details, refer to the US Fish & Wildlife Service *Best Practices for Migratory Bird Care during Oil Spill Response*.

Daily Reports

Daily summaries are submitted by the OWRO to summarize activities performed, impacted wildlife collected, patient totals in the Oiled Wildlife Response Facility, patients transferred, patients released, etc. This report is submitted to the members of the Incident Command Post. This report can be used to plan for the next operational period.

Daily briefings will also be conducted prior to every shift at the Stabilization Facility and/or Primary Care Center, typically in the morning and mid-day. The Wildlife Branch Director and Site Safety Officer will brief all OWRO personnel on safety considerations, work assignments, and general response updates.

Medical Records

The OWRO will be responsible for medical documentation of all animals collected, live and deceased. They may have their own digital/web-based data/reporting system like *Wildlife Rehabilitation MD (WRMD)* or they may keep paper records for each patient. Patient medical records will follow the animal from their initial exam until final disposition. Medical records should be kept secure whether digital or paper as they may be needed by law enforcement as evidence.

Wildlife Branch Operations

Assessment and Survey

Prioritization of Sensitive Species/Habitats

Oiled wildlife response operations must first start with a thorough assessment of the species at risk and sensitive habitats, as the loss of endangered/threatened species is one of the biggest environmental concerns following an uncontrolled release of contaminants. Assessment strategies are determined based on a combination of the origin/location of the spill, projection of the spill, and sensitive species/habitats at risk (see Species and Habitats at Risk section above). Booming, skimming and physical control of oil acts as the first line of defense, but proper assessment of all species and habitats are necessary for the mitigation and prevention of wildlife impacts by an oil spill. The OWRO will consult with wildlife trustees and/or SCAT (Shoreline Clean-up and Assessment Technique) teams to coordinate viewing of these habitats.

Survey Methods

Reconnaissance surveys should be utilized as soon as possible following the release of a spill so that the number, location, and type of species affected can be determined and relayed to key response personnel, including the Wildlife Branch Director, Environmental Unit Leader, and Situation Unit Leader. The location and number of wildlife (alive, dead, oiled and unoiled) should be plotted on a map; digitized maps are preferred, such as ERMA and Survey123 for multi-agency access to the information obtained during survey operations. The scope and frequency of subsequent surveys will be incident-specific.

Personnel performing surveys must be able to properly identify species, interpret behavioral characteristics that may indicate oiling (e.g. excessive preening, loafing and beaching from exhaustion/hypothermia, etc.), and have local knowledge of habitats and ecology. Utilizing a combination of OWRO staff, skilled observers, and volunteers will ensure an overall successful operation. All survey methods and operations must be authorized and coordinated through the Operations and Logistics Section. Examples of different survey methods are:

- Aerial Surveys – Helicopter, fixed wing aircraft, and drones

- Active Ground Surveys – Automobile, boats, on-foot patrol
- Passive Ground Surveys – Game cameras and monitoring equipment

Data Collection

Data collected from wildlife surveys are essential for determining next steps and tracking numbers and movement of species (both oiled and at-risk of oiling). This information is necessary to determine the proper implementation of wildlife field operations. After a survey, the information will be relayed to the Wildlife Branch Director, Environmental Unit, and Situation Unit to discuss next steps. This may involve pre-emptive capture of un-oiled but at-risk species, development of a hazing/deterrence plan, and priorities for physical capture of oiled wildlife. See the Documentation section of this annex for more information on data collection.

Hazing and Deterrence

Authorizations

A deterrence plan that employs many different methods of both audio and visual stimuli to dissuade animals from entering an at-risk area can be extremely helpful in prevention of oiled wildlife. The various methods and tools used can require certain permits, licenses, and trained operators. All deterrence activities will require authorization from appropriate natural resource management.

Certain tools, such as pyrotechnics, may require permits from the local Fire Marshall. All workers performing hazing and deterrence must have a minimum of 24-hour HAZWOPER training.

Techniques and Tools

The following factors should be considered when developing a hazing plan:

- Some animals are not candidates for hazing and deterrence, including animals that don't have an escape pathway, currently oiled animals, birds in catastrophic molt, and nesting birds. Pre-emptive capture and relocation may be more appropriate for these animals.
- Consider the environmental impact of chemicals and litter from hazing equipment.
- Avoid dispersing wildlife into areas that might become contaminated, being mindful of oil trajectory projections.

A variety of audio and visual stimuli should be utilized in order to prevent habituation. Deterrence is most effective if the entire area of concern can be hazed as continuously as possible, with various devices and intervals of disturbance. If this is not possible, careful reconsideration of a hazing program should be discussed before operations begin. Some devices may be operated automatically and can be used when personnel are limited, during bad weather, or overnight.

The following table lists a variety of techniques and tools that can be used for effective hazing/deterrence:

Table 9. Hazing/deterrence tools.

Tools	Audio	Visual	A & V	Exclusion
Bird Bombs, Screamers, Screamer Rocket Bangers	**X**			
Shell Crackers	**X**			
CAPA launcher and rockets	**X**			
Propane Cannons	**X**			
Distress and Alarm Calls	**X**			
Phoenix Wailer	**X**			
Mylar Tape		**X**		
Scarecrows		**X**		
Flags		**X**		
Balloons		**X**		
Lasers		**X**		
Lights		**X**		
Blowy Man		**X**		
ATV			**X**	
Aircraft – including drones			**X**	
Boats			**X**	
Overhead Lines				**X**
Netting				**X**
Fencing				**X**
Plastic Balls				**X**
Spikes/coils				**X**

Note: Utilizing a combination of tools and techniques will further dissuade wildlife by ensuring resistance to habituation. For example, you can use exclusion methods like fencing and netting in addition audio/visual stimuli like lasers and distress calls to maximize efforts.

Collection and Capture

Wildlife capture should be implemented as safely and early as possible to increase the survival rate of oiled animals. The period of time that oiled wildlife remain in the field is exponentially detrimental to their condition and repeated unsuccessful capture attempts may fatally exhaust an animal, so a well-developed capture plan is critical for animal survival.

Safety is paramount for both humans performing the capture and for the wildlife being captured. Field workers should have knowledge of handling requirements for the affected species to protect themselves and the animal; wild animals can be easily permanently injured if handled improperly and are prone to capture myopathy, which may be fatal. Weather and environmental conditions should also be considered before attempting to capture wildlife.

Wildlife capture rules:

- Safety always comes first.
- Ensure personnel are trained and familiar with wildlife capture and handling.
- Wear appropriate PPE and clothing for the field conditions, contaminant, and target species.
- Never work solo – utilize the buddy system and work in teams.
- Do not pursue wildlife until they are exhausted.
- Report any injuries.

Preemptive Capture

In some situations, pre-emptive capture may be necessary for wildlife that are at-risk and cannot be effectively removed using hazing, deterrence or exclusion from the area of concern. Before attempting preemptive capture, consult the USFWS and state wildlife trustees to obtain permission, particularly for T&E species. If immediate relocation is not appropriate, licensed wildlife rehabilitators may be authorized to temporarily hold and release preemptively captured wildlife.

Consider preemptive capture when:

- Animals cannot physically or behaviorally be removed from an at-risk area.
- Nesting birds and their chicks are at-risk of becoming oiled unless removed (note: pinniped nurseries and seabird rookeries are off limits for any type of capture).

Live Animal Capture

A variety of capture methods and techniques should be employed for successful results. Techniques will vary depending on species natural history and behavior, species priority (i.e. T&E species), weather, and terrain conditions.

Possible capture techniques include the following, among others:

- On-water capture using boats and nets
- Setting traps (e.g. foothold nooses, mammal live traps, pit traps for reptiles and amphibians, etc.)

- On-land capture using nets and sheets
- Corrals

Proper handling of captured wildlife is critical to prevent injury. Grabbing birds by the wings or allowing wings to flap freely can result in fractures, dislocations, or soft tissue damage that may warrant euthanasia. Some species require restraint of the feet and head to prevent handler injury. **Never tape an animal's mouth closed or tape its limbs together.** Never attempt to handle raptors without proper training. Once animals are captured, covering their head with a sheet or pillowcase and immediately placing the animal into a covered transport container will greatly reduce the animal's stress.

Appropriate containers should be available for captured wildlife, with the following characteristics:

- Ample ventilation
- Enough space for the animal to stand and spread their wings/limbs
- Bedding at the bottom of the carrier to secure the animal's footing and provide some absorption of oil
- A visual barrier between the animal and humans to reduce the animal's stress; this can be in the form of a sheet draped over the carrier as long as the sheet is breathable and able to be secured.
- Labelled with appropriate information – see Documentation section

Most wildlife should be placed in a carrier alone, except for social species or precocial babies. Be sure to consider ambient temperature to prevent overheating or hypothermia and keep carriers in a quiet place to reduce stress.

Carcass collection

Carcass collection prevents secondary oiling of other animals and ingestion of oil by predators. Carcasses may also act as evidence in investigations about the incident. A carcass collection procedure should be developed as part of the Wildlife Management Plan, including a chain of custody protocol, in coordination with the US Fish & Wildlife Service. See the Documentation section for information about carcass labelling. Carcasses should be wrapped in foil followed by paper bags and locked in a refrigerator or freezer. All carcasses should be processed in the same manner as live animals with recorded observations on the extent of oiling and evidence collection.

Animal Transport

Oiled wildlife that have been captured and labeled should be brought to the nearest care facility as soon as possible. In some cases, wildlife may need field stabilization and others may be able to go directly to a primary care facility; this determination will be at the discretion of the OWRO.

Vehicles that transport oiled wildlife should have adequate ventilation and a separate cab and cargo space so that humans are not enclosed with harmful vapors. Animal containers must be secured to prevent moving around during transport. Transport personnel must be mindful of the

ambient temperature in the cargo area to prevent animals from overheating or developing hypothermia.

Rehabilitation

Field Stabilization

OWRO personnel will assess animals in the field and determine if they require stabilizing medical treatments before transport. If needed, a field stabilization station will be set up using trailers or a pop-up tent and heating/cooling elements as appropriate. Only personnel with training in veterinary medicine will perform stabilizing treatments. Field stabilization is provided to animals in critical condition and animals who will remain in the field for longer than 2-3 before transport. Field stabilization does not include washing the animals or taking blood samples.

Steps for field stabilization:

- Gross contaminant removal (clearing the eyes, nostrils/nares, and mouth of bulk oil)
- Body temperature regulation
- Fluid therapy
- Minimize stress for the animal

Triage

Oiled wildlife brought to the Primary Care Center will be triaged so that animals are treated according to their condition and species priority. Full examinations will not be performed until the animals are stable. Some patients may require humane euthanasia if injuries are too severe and decontamination and rehabilitation is not possible. The Wildlife Management Plan should include a euthanasia plan developed by the wildlife veterinarian, OWRO, and state/federal wildlife trustees. Euthanasia guidelines may also be found in the federal and state wildlife rehabilitation permits held by the OWRO.

Examination/Initial Treatment and Pre-Wash Care

Each patient will be assigned an ID number, a medical log will be created, and evidence will be collected as described in the Documentation section of this annex. Full physical examinations will be conducted under veterinary supervision, including observations on the animal's behavior, extent of oiling, dehydration, temperature, body condition, and any overt injuries. An ongoing treatment plan will be developed in consultation with the wildlife veterinarian.

Animals typically need 2-3 days of supportive treatments before they are fit to undergo decontamination. Species-specific housing will be provided according to the International Wildlife Rehabilitation Council/National Wildlife Rehabilitators Association *Standards for Wildlife Rehabilitation* and daily husbandry will be provided for all animals in care. OWRO personnel and the wildlife veterinarian will determine when an animal is a candidate for decontamination.

Decontamination

Wildlife decontamination should only be performed by qualified individuals; attempting to wash animals without prior training may lead to human or animal injury, repeat washes (an animal

should ideally only be washed once), or even the death of the animal. Proper PPE must be worn in order to protect the wash team, including chemical-resistant coveralls and gauntlet gloves, eye protection, and waterproof boots.

Once patients are deemed stable enough for a wash, OWRO personnel will determine the necessary protocol for decontamination based on the contaminant, degree of weathering, and pre-treatments needed to break down the oil. Wash techniques will vary depending on the type of animal and the degree of the oiling. Some animals may need to be sedated or anesthetized during the wash process at the discretion of the wildlife veterinarian.

The following water conditions are required for successful decontamination:

- Temperature between 104-108°F
- Hardness between 2-5 grains per gallon
- Pressure between 40-60 psi for rinsing

Once patients have been decontaminated and rinsed, they must be given ample time in drying pens.

Pre-Release Conditioning

Once animals have been fully decontaminated, they will need additional supportive care before they are ready for release. Some animals, like frogs and snakes, may be able to be released within days after decontamination. Other animals, like loons and diving ducks, may need weeks in enclosures with pool access to develop adequate waterproofing for release. A plan for pre-release conditioning will be developed for each animal by OWRO personnel. If the Primary Care Center cannot meet the needs of the animals for pre-release care, the animals will be transferred to an appropriate facility (see Facility Requirements section).

All animals must be thoroughly evaluated before release can be considered. In general, the following criteria must be met for an animal to be released back into the wild:

- Adequate physical fitness and normal behavior for the species and lifestyle
- Full recovery from any injury or illness
- Acclimation to the outdoors – including impeccable waterproofing for birds
- Body weight within 10% of the species normal range
- Normal blood values for the species

Release

The release of any oil-impacted wildlife must be approved through the appropriate federal and state wildlife trustees. A release plan should be created by the OWRO and submitted to the Environmental Unit. If animals do not meet release criteria at the conclusion of wildlife response operations, they may be transferred for additional rehabilitation, euthanized, or placed in a long-term facility. This decision should be made by the OWRO in conjunction with federal and state wildlife trustees.

The Unified Command will give the final authorization and approval for release, but the release site must first meet the following criteria:

- No oil contamination present
- No risk of recontamination
- Same general geographic area of capture, if possible
- Appropriate seasonal range for the species (important consideration during migration periods)
- Available, natural, and uncontaminated food sources
- Minimal human disturbance (including boats and noise from spill response operations)
- Favorable weather conditions/forecast
- Appropriate time of day for the species

Post-release monitoring can provide valuable data to evaluate the success of decontamination and rehabilitation. Methods for post-release monitoring include USFWS bands for migratory birds, auxiliary bands, and GPS or radio telemetry collars/backpacks. These methods typically require additional state and federal permits.

Wildlife Branch Demobilization

As the spill is contained and contaminated areas are cleaned, the potential for additional wildlife to be impacted will decline and the wildlife field operations can be scaled back and eventually ended. Rehabilitation operations will continue after that until all impacted animals have been rehabilitated and released or transferred/placed. It is not unusual for wildlife operations to demobilize after other Operations Section responders.

The OWRO and the Operations Section will jointly develop a demobilization plan for the Primary Care Center and any Stabilization Facility which will either be returned to their pre-incident condition or put in a stand-by mode if the potential for additional oiling of animals is significant. The demobilization plan will include:

- A schedule for reducing staff and volunteers
- Determination of what will happen with any animals still in care
- Disposal or redistribution of prescribed medications
- A process to inventory, sanitize, and/or decontaminate any remaining supplies and equipment
- A plan to return, redistribute, or store remaining supplies and equipment as appropriate
    - Supplies and equipment may be demobilized before the conclusion of wildlife operations
- Coordination with the Wildlife Branch Director and law enforcement on transferring documentation and evidence from the Primary Care Center

ESA Section 7

Requirements

9716: Inter-agency Memorandum of Agreement Regarding Oil Spill Planning & Response Activities Under the Federal Water Pollution Control Act's National Oil and Hazardous Substances Pollution Contingency Plan and the Endangered Species Act

I. INTRODUCTION

A. Parties. The Parties to this agreement are the U.S. Coast Guard (USCG), the U.S. Environmental Protection Agency (USEPA), the Department of the Interior (DOI) Office of Environmental Policy and Compliance, the U.S. Fish and Wildlife Service (USFWS), and the National Oceanic and Atmospheric Administration's (NOAA's) - National Marine Fisheries Service (NMFS) and National Ocean Service (NOS).

B. The Parties have conducted a review of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) and associated oil spill response activities to coordinate their actions under Section 1321(d) of the Clean Water Act and Section 7(a)(1) of the Endangered Species Act, as amended (16 U.S.C. 1531 et seq.) (ESA). Section 1321(d) of the Clean Water Act establishes the NCP and assigns responsibilities to Federal agencies in mitigating damage from oil and hazardous materials spills, including the conservation of fish and wildlife. Section 7(a)(1) of the ESA requires all Federal agencies, in consultation with and with the assistance of the Secretaries of the Interior or Commerce, as appropriate, to review their programs and utilize their authorities in furtherance of the purposes of the ESA by carrying out programs for the conservation of listed species. As a result of this review, recommended procedures have been developed that will achieve better conservation of listed species and critical habitat during implementation of oil spill response activities.

C. This agreement provides a general framework for cooperation and participation among the Parties in the exercise of their oil spill planning and response responsibilities. Following the recommended procedures presented in this agreement will better provide for the conservation of listed species, improve the oil spill planning and response procedures delineated in the NCP, and ultimately streamline the process required by Section 7(a)(2) of the ESA.

II. PURPOSE

A. This agreement is intended to be used at the area committee level primarily to identify and incorporate plans and procedures to protect listed species and designated critical habitat during spill planning and response activities. Proactive regional planning may also take into consideration concerns for proposed and candidate species, as well as listed species' habitat not yet designated as critical.[1]

[1] Adverse effects on non-designated critical habitat used by listed species has a potential for having an adverse affect on these listed species. Therefore, planners should consider these areas if information is available.

B. This agreement coordinates the consultation requirements specified in the ESA regulations, 50 CFR 402, with the pollution response responsibilities outlined in the NCP, 40 CFR 300. It addresses three areas of oil spill response activities: pre-spill planning activities, spill response event activities, and post-spill activities. The agreement identifies the roles and responsibilities of each agency under each activity. By working proactively before a spill to identify potential effects of oil spill response activities on listed species and critical habitat, and jointly developing response plans and countermeasures (response strategies) to minimize or avoid adverse effects, impacts to listed species and critical habitat should be reduced or avoided completely. Should a spill occur, response plans and countermeasures will be used to implement response actions to minimize damage from oil discharges in a manner that reduces or eliminates impacts to listed species and critical habitat. In the event that oil spill response actions may result in effects on listed species or critical habitat, the agreement provides guidance on how to conduct emergency consultation under the ESA. It also describes the steps for completing formal consultation, if necessary, after the case is closed, if listed species or critical habitat have been adversely affected.

C. The goal of this agreement is to engage in informal consultation wherever possible during planning and response. With adequate planning and ongoing, active involvement by all participants, impacts to listed species and critical habitat and the resulting need to conduct subsequent ESA Section 7(a)(2) consultations will be minimized or obviated.

III. LEGAL AUTHORITIES

A. The Federal Water Pollution Control Act (FWPCA), 33 U.S.C. § 1321., requires that when a spill occurs, the President take such action as necessary to ensure effective and immediate removal of a discharge, and mitigation or prevention of a substantial risk of a discharge of oil into the waters of the United States. The National Contingency Plan (NCP), 40 CFR Part 300, prepared in accordance with the FWPCA, assigns duties to Federal agencies to protect the public health and welfare, including fish, wildlife, natural resources and the public. The NCP designates the Federal On Scene Coordinator (FOSC) as the person responsible for coordinating an oil spill response. (The abbreviation OSC is used in the NCP, while the abbreviation for Federal On Scene Coordinator is FOSC in this agreement.) Nothing in this agreement limits the authority of the Federal On Scene Coordinator as defined in the NCP.

B. The Endangered Species Act of 1973 (ESA), as amended, 16 U.S.C. §1531 et seq., provides a means to protect threatened and endangered species and the ecosystems upon which they depend. The ESA requires that Federal agencies insure that the actions they authorize, fund, or carry out do not jeopardize listed species or adversely modify their designated critical habitat. Regulations for conducting Section 7 consultation are set forth in 50 CFR Part 402.

IV. DEFINITIONS

The following definitions apply to this agreement and are taken from the definitions contained in either the NCP or the March 1998 USFWS & NMFS Endangered Species Consultation Handbook. For definitions of terms not listed below, refer to the USFWS & NMFS Endangered Species Consultation Handbook and the NCP as appropriate.

Area Committee - the entity appointed by the President consisting of members from qualified personnel of Federal, state, and local agencies with responsibilities that include preparing an area contingency plan for an area designated by the President. The chairs of the Area Committee are the USCG for coastal and Great Lakes plans, and the USEPA for inland plans. In some instances the Regional Response Team (RRT) may act as the Area Committee. In this MOA, the term Area Committee also includes the RRT acting as the Area Committee.

Area Contingency Plan (ACP) - the plan prepared by an Area Committee (or the RRT acting as the Area Committee) that is developed to be implemented in conjunction with the NCP and Regional Contingency Plan (RCP), in part to address removal of a worst case discharge and to mitigate or prevent a substantial threat of such a discharge from a vessel, offshore facility, or onshore facility operating in or near an area designated by the President. A detailed annex containing a Fish and Wildlife and Sensitive Environments Plan prepared in consultation with the USFWS, NOAA, and other interested natural resource management agencies should be incorporated into each ACP. In this MOA, the term ACP also includes sub-area ACP's, sub-area contingency plans, geographic response plans and geographic response strategies as per 40 CFR 300.210.

Biological Assessment - information prepared by or under the direction of the Federal action agency (USCG or USEPA) regarding: 1) listed and proposed species and designated critical habitat that may be affected by proposed actions; and, (2) the evaluation of potential effects of the proposed actions on such species and habitat.

Biological Opinion - document which includes: (1) the opinion of the USFWS or NMFS as to whether or not a Federal action is likely to jeopardize the continued existence of listed species, or result in the destruction or adverse modification of designated critical habitat; (2) a summary of the information on which the opinion is based; and (3) a detailed discussion of the effects of the action on listed species or designated critical habitat. This document will also contain an incidental take statement, that, if appropriate, exempts the Federal actions from the ESA Section 9 take prohibitions.

Candidate species – plant and animal taxa considered for possible addition to the List of Threatened and Endangered Species.

Case is Closed – When removal operations are complete in accordance with 40 CFR 300.320(b).

Critical habitat - areas designated by the USFWS and NMFS pursuant to Section 4 of the ESA for the purposes of identifying areas essential for the conservation of a threatened or endangered species and which may require special management considerations.

Emergency Consultation – an expedited consultation process that takes place during an emergency (natural disaster or other calamity) (50 CFR 402.05). The Services have determined that oil spill response activities qualify as an emergency action. The consultation may be initiated informally. The emergency continues to exist until the removal operations are completed and the case is closed in accordance with 40 CFR 300.320(b). The FOSC will continue to conduct emergency consultations, if needed, until the emergency is over and the case is closed. Formal, or informal, consultation is initiated after the emergency is over, at which time the USFWS and/or NMFS evaluates the nature of the emergency actions, the justification for the expedited consultation, and any impacts to listed species and their habitats.

Federal On Scene Coordinator (FOSC) - the Federal official predesignated by USEPA or the USCG to coordinate and direct responses under the FWPCA as defined in the NCP.

Formal Consultation[2] - a process between USFWS or NMFS and the Federal action agency (USCG or USEPA) that: (1) determines whether a proposed Federal action is likely to jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat; (2) begins with a Federal agency's written request and submission of a complete Section 7 consultation initiation package; and (3) concludes with the issuance of a biological opinion and incidental take statement, as appropriate, by either of the Services. If a proposed Federal action may affect a listed species or designated critical habitat, formal consultation is required (except when the Services concur, in writing, that a proposed action "is not likely to adversely affect" listed species or designated critical habitat. See informal consultation).

Incidental Take - take of listed fish or wildlife species that results from, but is not the purpose of, carrying out an otherwise lawful activity conducted by a Federal agency or applicant.

Informal Consultation - an optional process that includes all discussions and correspondence between the USFWS or NMFS and the Federal agency (USCG or USEPA) or designated non-Federal representative, prior to formal consultation, to determine whether a proposed Federal action may affect listed species or critical habitat. This process allows the Federal agency to utilize the Services' expertise to evaluate the agency's assessment of potential effects or to suggest possible modifications to the proposed action, which could avoid potential adverse effects. If a proposed Federal action may affect a listed species or designated critical habitat, formal consultation is required (except when the Services concur, in writing, that a proposed action "is not likely to adversely affect" listed species or designated critical habitat).

[2] Formal consultation can occur during planning or after the conclusion of emergency consultation if listed species or critical habitat have been affected.

Listed Species – for the purposes of this MOA, any species of fish, wildlife or plant, which has been determined to be endangered or threatened under Section 4 of the ESA.

National Contingency Plan (NCP) – National Oil and Hazardous Substances Pollution Contingency Plan. The NCP is a national plan that provides the organizational structure and procedures for preparing for and responding to discharges of oil and releases of hazardous substances, pollutants and contaminants. The NCP is set forth in 40 CFR 300.

National Response Team (NRT) - a national team, defined under the NCP, responsible for national planning, policy, and coordination for hazardous substance and oil spill preparedness and response, consisting of representatives from agencies named in 40 CFR 300.175(b).

Regional Response Team (RRT) - a regional team of agency representatives that acts in two modes: the standing RRT and incident specific RRT. The Co-chairs are the USCG and USEPA. The standing team is comprised of designated representatives from each participating Federal agency, state governments and local governments (as agreed upon by the states). Incident-specific teams are formed from the standing team when activated for a response. The role of the standing RRT includes establishing regional communications and procedures, planning, coordination, training, evaluation, preparedness and related matters on a region-wide basis. It also includes assisting Area Committees in coordinating these functions in areas within their specific regions. The role and composition of the incident-specific team is determined by the operational requirements of the response. During an incident, it is chaired by the agency providing the FOSC.

Services – Term used to refer to both the USFWS and NMFS.

V. PROCEDURES

Oil spill planning and response procedures are set forth in the NCP. This agreement is intended to facilitate compliance with the ESA without degrading the quality of the response conducted by the FOSC, to improve the oil spill planning and response process, and ensure continued inter-agency cooperation to protect, where possible, listed species and critical habitat.

A. PRE-SPILL PLANNING

(1) While drafting Area Contingency Plans themselves may not result in effects to listed species, actions implemented under the plans may. It is essential that the Area Committee engage USFWS and NMFS during the ACP planning process while developing or modifying the ACP and response strategies. This informal consultation can be used to determine the presence of listed species or critical habitat, and the effects of countermeasures, and to ensure that measures to reduce or avoid impacts to listed species and critical habitats during oil spill response activities are developed. By consulting on the anticipated effects prior to implementing response actions, decisions can be made rapidly during the spill, harm from response actions can be

minimized, and implementation of response strategies specifically designed to protect listed species and critical habitat can be achieved.

(2) The pre-spill planning process is shown as a flow chart in Appendix A. The Area Committee Chair will request, in writing, that endangered species expertise and a species list be provided by the Services.[3] The request should also describe the area and include a general description of the countermeasures being considered and the planning process to be used (e.g., a workgroup). In order to document the request for consultation and planning involvement, the request shall be sent to both NOAA and USFWS. To obtain NMFS assistance, a request should be sent to the Department of Commerce (DOC) RRT representative, with a copy to the NOAA Scientific Support Coordinator (SSC) and the NMFS Regional Field Office. For USFWS support, a request should be sent to the local USFWS field office(s), with a copy to the USFWS Regional Response Coordinator (RRC) at the appropriate USFWS Regional Office(s) and the DOI RRT representative. It is the responsibility of the USFWS RRC, acting through the Ecological Services Assistant Regional Director, and the NOAA SSC to act as a liaison between the respective Service and the Area Committee. USFWS and NMFS will orally respond to the request within 30 days of receipt and provide a written response within 60 days. The response should include designation of a listed species expert to assist the Area Committee.

(3) If listed species or critical habitat are present in the planning area being considered the Area Committee should use a planning process that ensures engagement of Service experts.[4] This process shall ensure that the appropriate participants jointly gather and analyze the information needed to complete the Planning Template in Appendix C. This planning process constitutes informal consultation.[5] The goals of this planning process are to identify the potential for oil spill response activities to adversely affect listed species and critical habitat and to identify for inclusion in the ACP information on sensitive areas, emergency response notification contacts, and any other information needed. Methods should be developed to minimize identified adverse effects and, where necessary, the plan should be modified accordingly. If specific sources of potential adverse effects are identified and removed, the Services will provide a concurrence letter and Section 7(a)(2) requirements will be deemed to have been met.[6]

(4) If, after the process in Appendix C has been followed, it cannot be determined that adverse effects will not occur during a response action, the USCG or USEPA, as appropriate, will initiate formal consultation using the information gathered in Appendix C; this information will be used by the Services to complete formal

[3] 40 CFR 300.170(a).
[4] Process options include using an informal workgroup; formal workgroup, Environmental Risk Assessment process, or other process based on Area Committee needs.
[5] This process does not negate any regional consultations that have already occurred, nor alter the strategies/procedures in the ACP until the ACP is officially modified in consultation with USFWS or NMFS.
[6] Letter is required for the administrative record. See Appendix E.

consultation.[7] This will be a programmatic consultation that generally addresses oil spill response activities at issue in the plan area. At times when specific information is available about certain oil spill response methods and listed species and critical habitat, it may be possible to pre-approve particular activities that may be implemented in the event there is insufficient time to initiate emergency consultation before the need to take action.[8]

(5) All parties recognize that development and modification of the ACP is an ongoing process. Changes, including modifications to response actions or changes to the species list, should be addressed regularly through a dynamic planning process. The Services should contact the Area Committee or workgroup if they become aware of newly listed species that may be affected by planned response activities. The Area Committee should likewise notify the Services of changes to planned response activities. The Area Committee or workgroup should evaluate any changes and assess the need for additional consultation as needed.

B. OIL SPILL RESPONSE

During an oil spill event which may affect listed species and/or critical habitat, emergency consultations under the ESA are implemented (50 CFR 402.05) for oil spill response actions.[9] Emergency consultation may be conducted informally through the procedures that follow (See Appendix A). Emergency consultation procedures allow the FOSC to incorporate listed species concerns into response actions during an emergency. "Response" is defined in this agreement as the actions taken by the FOSC in accordance with the NCP. The FOSC conducts response operations in accordance with the NCP and agreement established in the ACP.

(1) As per the NCP and ACP, the FOSC will notify the RRT representatives of DOI and DOC through the established notification process regardless of whether listed species or critical habitat is present. Upon notification, the DOC and DOI representatives shall contact the NOAA SSC and RRC, respectively, and other appropriate Service contacts as provided in internal DOC or DOI plans, guidance, or other documents. If established in the ACP, the FOSC may also contact the Service regional or field offices directly (see Section V(A)(3) above). If listed species and/or critical habitat are present or could be present, the FOSC shall initiate emergency consultation by contacting the Services. The NOAA SSC and RRC shall coordinate appropriate listed species expertise. This may require timely on-scene expertise from the Services' local field offices. These Service representatives may, as appropriate, be asked by the FOSC to participate within the FOSC's Incident Command System and provide information to the FOSC.[10]

---

[7] Letter is required for the administrative record. See Appendix E.

[8] Due to time constraints associated with spill response, this does not mean that immediate spill response actions cannot occur to meet the requirements of 40 CFR 300.317. However, planning should address specific procedures for initiating emergency consultation for activities that are pre-approved and for those that have not been pre-approved.

[9] Based on pre-spill planning or discovered during the response.

[10] 40 CFR 300.175(b)(7) & (b)(9); 40 CFR 300.305(e).

(2) The ACP, including any agreed upon references cited in the ACP, should form the basis for immediate information on response actions. As part of emergency consultation, the Services shall provide the FOSC with any timely recommendations to avoid and/or minimize impacts to listed species and critical habitat.[11] The NOAA SSC should also be involved in these communications as appropriate. If incidental take is anticipated, and if no means of reducing or avoiding this take are apparent, the FOSC should also be advised and the incidental take documented. If available, the FOSC should consider this information in conjunction with the national response priorities established in the NCP.[12] The FOSC makes the final determination of appropriate actions.

(3) It is the responsibility of both the FOSC and the Services' listed species representatives to maintain a record of written and oral communications during the oil spill response. The checklist contained in Appendix B is information required to initiate a formal consultation in those instances where listed species and/or critical habitat have been adversely affected by response actions.[13] If it is anticipated that listed species and/or critical habitat may be affected, the FOSC may request that the USFWS and/or NMFS representative to the Incident Command System oversee and be responsible for the gathering of the required information in Appendix B while the response is still ongoing.[14] The FOSC may also choose to designate another individual to be responsible for collecting the information.[15] Although in some instances the drafting of information for Appendix B may be completed after field removal operations have ceased, it is anticipated that collection of the information should be complete before the case is officially closed and that no further studies will be necessary.

(4) It is the responsibility of the FOSC to notify the Services' representatives in the Incident Command System of changes in response operations due to weather, extended operations, or some other circumstance. It is the responsibility of the Services to notify the FOSC of seasonal variances (e.g., bird migration), or other natural occurrences affecting the resource. If there is no Service representative in the Incident Command System, the FOSC will ensure that the NOAA SSC and/or DOI representative to the RRT remains apprised of the situation. The Services will continue to offer recommendations, taking into account any changes, to avoid jeopardizing the continued existence of listed species or adversely modifying critical habitat, and to minimize the take of listed species associated with spill response activities.

---

[11] See Section 8.1 of the USFWS & NMFS Endangered Species Consultation Handbook (http://endangered.fws.gov/consultations/s7hndbk/s7hndbk.htm).
[12] 40 CFR 300.317 National Response Priorities.
[13] See Section 8.2(B) of the USFWS & NMFS Endangered Species Consultation Handbook.
[14] If requested by the FOSC, the NOAA Scientific Support Coordinator (SSC) may coordinate this data collection.
[15] See Appendix D for example Pollution Removal Funding Authorization (PRFA) Statement of Work language.

C. POST RESPONSE

If listed species or critical habitat have been adversely affected by oil spill response activities, a formal consultation is required, as appropriate.[16] Informal emergency consultation shall remain active until the case is closed. The FOSC will initiate consultation on the effect of oil spill response activities (not the spill itself) after the case is closed. Every effort shall be made to ensure that relevant information generated as part of the consultation process is made available for use in the Natural Resource Damage Assessment (NRDA) process. (Note: NRDA activities are separate from this consultation.)

(1) After the FOSC determines that removal operations are complete in accordance with 40 CFR 300.320(b), the impacts of the response activities on listed species and critical habitat will be jointly evaluated by the FOSC and the Services.

(2) If listed species or critical habitat were adversely affected by oil spill response activities, the FOSC will follow the procedural requirements of 50 CFR 402.05(b) (see Appendix A). The document developed by following Appendix B, information required to initiate a formal consultation following an emergency, should be included with a cover letter to the Services requesting consultation and signed by the FOSC. The FOSC will work with the Services and the NOAA SSC, as appropriate, to ensure that Appendix B is complete.[17] This document comprises the FOSC's formal request for consultation.

(3) The Services normally issue a biological opinion within 135 days of receipt of the Section 7 consultation request (50 CFR 402.14). When a longer period is necessary, and all agencies agree, the consultation period may be extended. The final biological opinion will be prepared by the Services and provided to the FOSC, USFWS RRC, NOAA SSC, DOI and DOC RRT members, and the Area Committee Chair so that recommendations can be reviewed by the Area Committee, and where appropriate, implemented to minimize and/or avoid effects to listed species and critical habitat from future oil spill response actions.[18] The result of the consultation should be considered by the FOSC for inclusion in a lessons learned system so changes can be made to the ACP, as necessary, for the benefit of future oil spill response actions. If such changes to the ACP modify the anticipated effects to listed species or critical habitat, the Services should appropriately document the anticipated changes in future effects and complete any appropriate administrative steps.

[16] If only proposed species or proposed critical habitat have been adversely affected, a formal consultation is not required; however, ESA conference procedures should be followed as appropriate. See the USFWS & NMFS Endangered Species Consultation Handbook for conference information.
[17] The NOAA SSC may also assist.
[18] Recommendations may also be provided for addressing effects caused by spill response actions. This information should be provided to the NRDA process as appropriate.

VI. Points of Contact. The following are the points of contact for each Party:

USCG: Chief, Office of Response, Coast Guard Headquarters (G-MOR), (202) 267-0516.

USEPA: Oil Program Center, U.S. Environmental Protection Agency, (703) 603-8823.

NOAA - NMFS: Section 7 Coordinator, Endangered Species Division, Office of Protected Resources, (301) 713-1401.

USFWS: National Spill Response Coordinator, U.S. Fish and Wildlife Service, Division of Environmental Quality, (703) 358-2148.

NOAA - NOS: Director, Office of Response and Restoration, (301) 713-2989 x101.

DOI: Office of Environmental Policy and Compliance, (202) 208-6304.

VII. Funding and Resources. This agreement is not a fiscal or funds obligation document. Nothing in this agreement shall be construed as obligating any of the Parties to the expenditure of funds in excess of appropriations authorized by law or otherwise commit any of the Parties to actions for which it lacks statutory authority. It is understood that the level of resources to be expended under this agreement will be consistent with the level of resources available to the Parties to support such efforts. Any activities involving reimbursement or contribution of funds between the Parties to this agreement will be handled in accordance with applicable laws, regulations and procedures. Such activities will be documented in separate agreements with specific projects between the Parties spelled out. The separate agreements will reference this general agreement.

VIII. Effective Date. The terms of this agreement are effective upon signature by all Parties.

IX. Modification. This agreement may be modified upon the mutual written consent of the Parties.

X. Termination. The terms of this agreement, as modified, with the consent of all Parties, will remain in effect until terminated. Any Party upon 60 days written notice to the other Parties may terminate their involvement in this agreement.

Inter-agency Memorandum of Agreement Regarding Oil Spill Planning and Response Activities Under the Federal Water Pollution Control Act's National Oil and Hazardous Substances Pollution Contingency Plan and the Endangered Species Act

Approved By: **Date**:

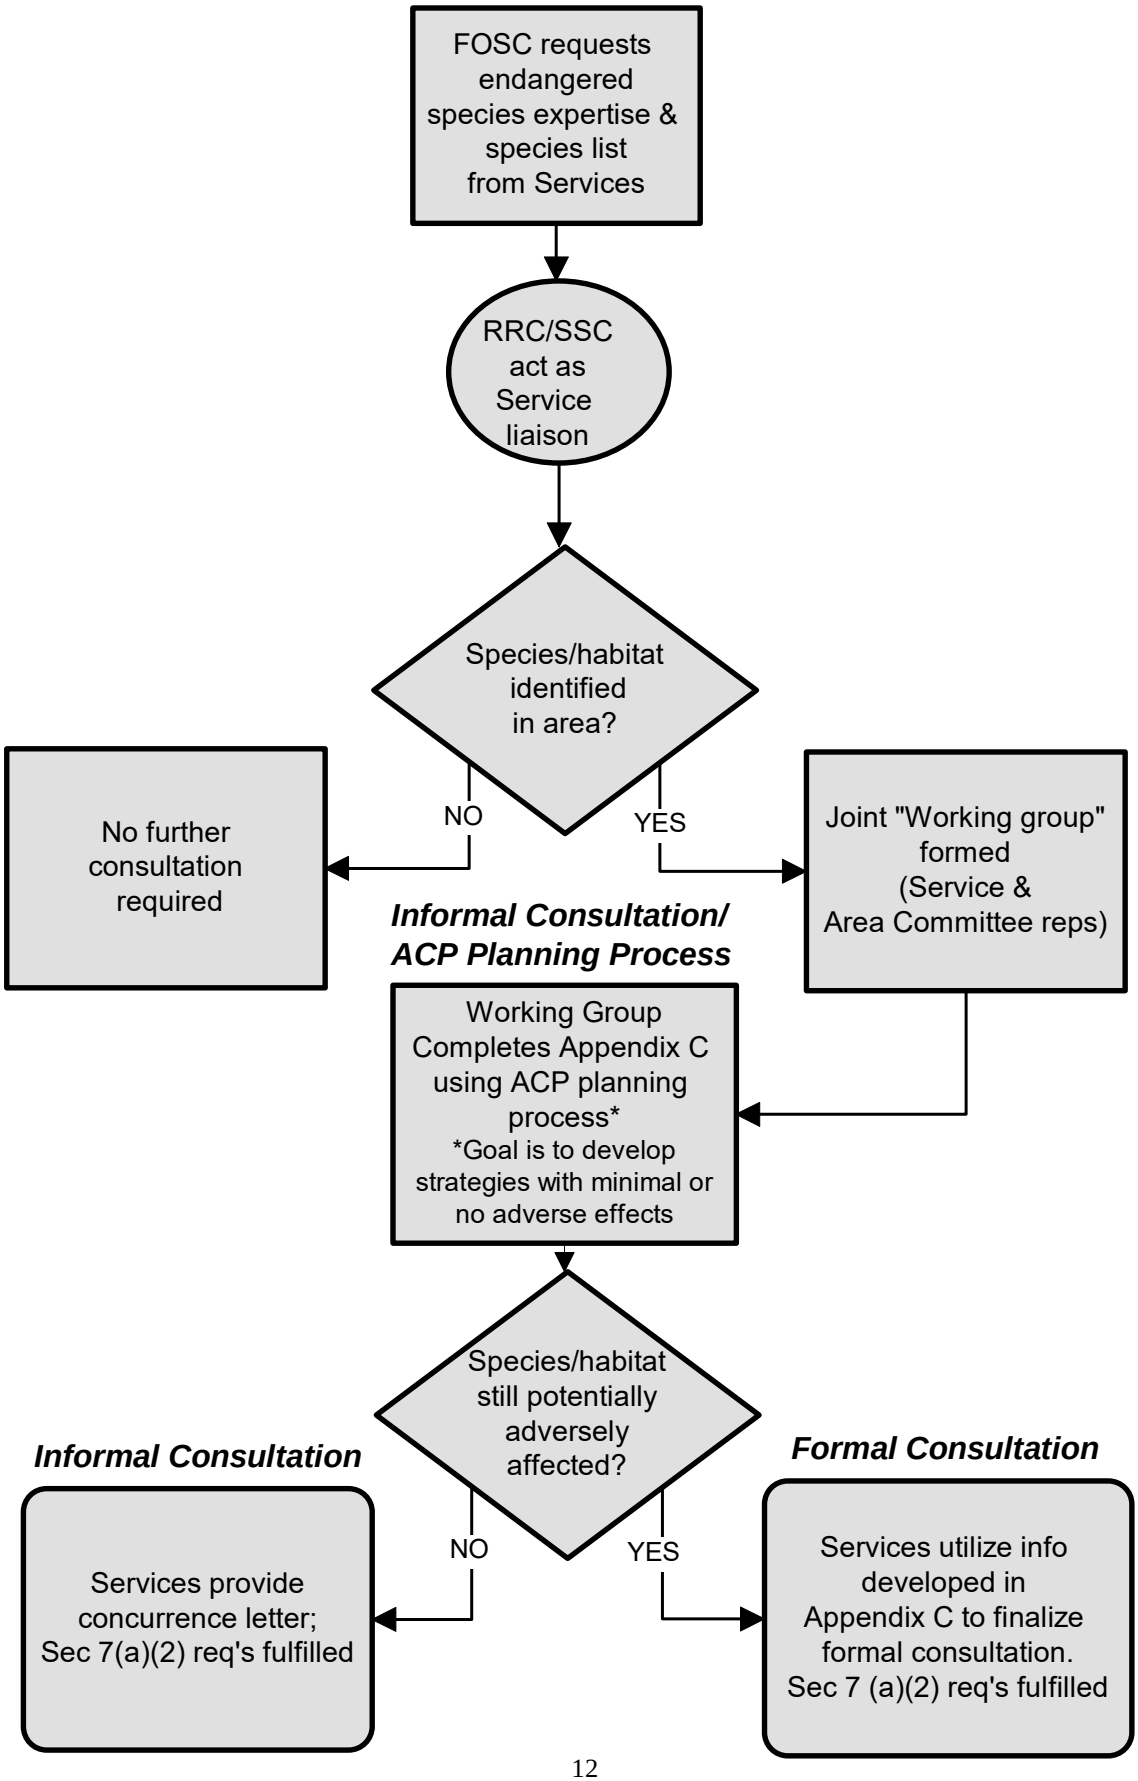
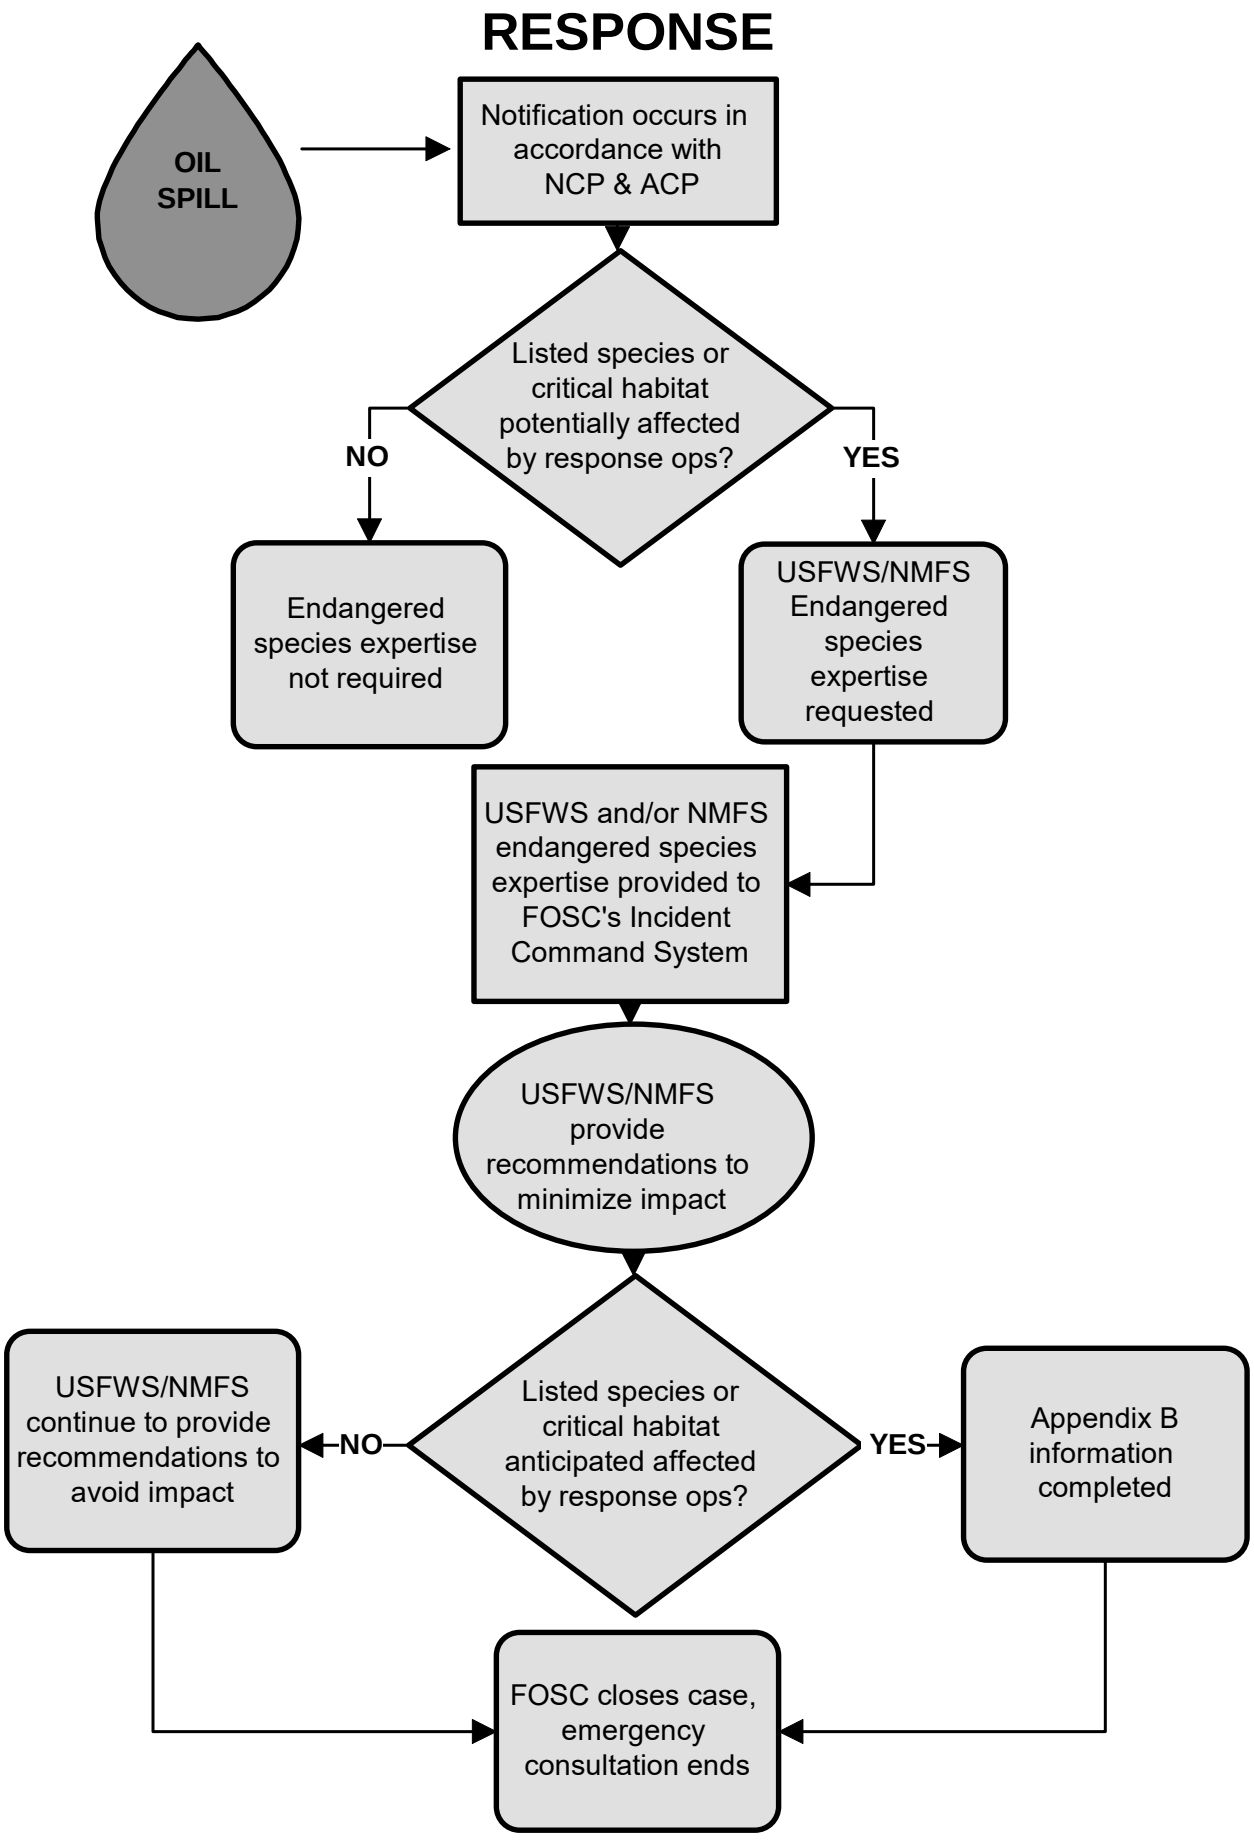
National Oceanic and Atmospheric Administration — 5/30/01

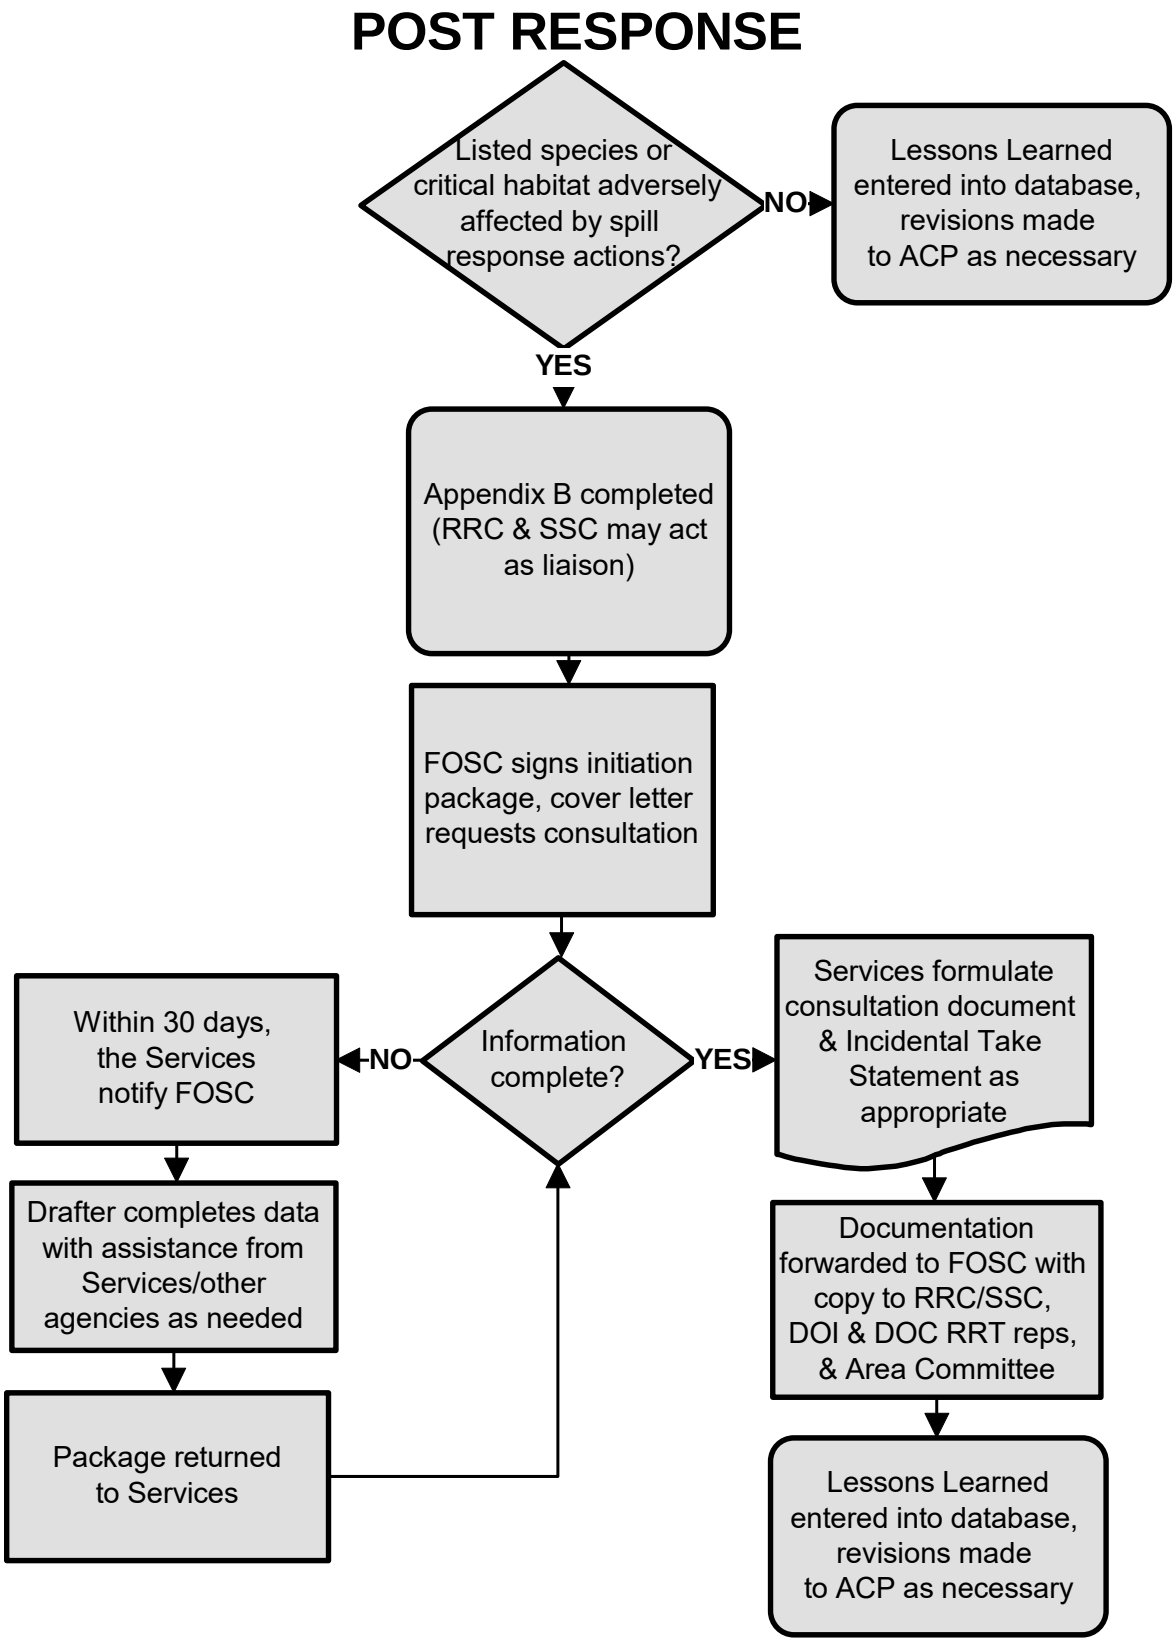
Director
Office of Environmental Policy and Compliance
Department of the Interior — 6/13/01

PRE-SPILL PLANNING





RESPONSE
OIL SPILL
Notification occurs in accordance with NCP & ACP
Listed species or critical habitat potentially affected by response ops?
NO
YES
Endangered species expertise not required
USFWS/NMFS Endangered species expertise requested
USFWS and/or NMFS endangered species expertise provided to FOSC's Incident Command System
USFWS/NMFS provide recommendations to minimize impact
Listed species or critical habitat anticipated affected by response ops?
NO
YES
USFWS/NMFS continue to provide recommendations to avoid impact
Appendix B information completed
FOSC closes case, emergency consultation ends



POST RESPONSE
Listed species or critical habitat adversely affected by spill response actions?
NO
Lessons Learned entered into database, revisions made to ACP as necessary
YES
Appendix B completed (RRC & SSC may act as liaison)
FOSC signs initiation package, cover letter requests consultation
Information complete?
NO
Within 30 days, the Services notify FOSC
Drafter completes data with assistance from Services/other agencies as needed
Package returned to Services
YES
Services formulate consultation document & Incidental Take Statement as appropriate
Documentation forwarded to FOSC with copy to RRC/SSC, DOI & DOC RRT reps, & Area Committee
Lessons Learned entered into database, revisions made to ACP as necessary

APPENDIX B

EMERGENCY CONSULTATION
INFORMATION CHECKLIST IN ANTICIPATION OF FOLLOW-UP FORMAL CONSULTATION (50 CFR 402.05)

As soon as practicable after the emergency is under control, which occurs when the case is closed, the FOSC initiates consultation (either formal or informal, as appropriate) with the Services if listed species and/or critical habitat have been affected. The FOSC should ensure that the following checklist is completed before the case is closed. After the case is closed, this information along with a cover letter requesting consultation will be sent to the Services.

1. Provide a description of the emergency (the oil spill response).

2. Provide an evaluation of the emergency response actions and their impacts on listed species and their habitats, including documentation of how the Services' recommendations were implemented, and the results of implementation in minimizing take.

3. Provide a comparison of the emergency response actions as described in #2 above with the pre-planned countermeasures and information in the ACP.

APPENDIX C

PLANNING TEMPLATE

One of the goals of the Area Contingency Plan (ACP) planning process is to develop strategies or actions that reduce the potential for planned oil spill response activities to adversely affect listed species and designated critical habitat. The planning process may also develop strategies that purposefully protect these resources. The following template is recommended for use by a working group of both Service and Area Committee representatives to develop a document that 1) is used to complete consultation pursuant to Section 7 (a)(2) of the Endangered Species Act of 1973, as amended, and 2) produces information to be included in the appropriate sections of the ACP. To streamline the consultation process, the various sections of this document could be drafted during the planning process and used to develop or modify the ACP.[19] This development process will assist all parties in gaining a thorough understanding of the actions under review and provide opportunities for any Section 7 consultation related issues to be raised and addressed in the planning process, rather than during the oil spill response action.

This template is intended to guide the thought process of creating consultation documents and incorporates content requirements set forth in 50 CFR 402.12 as well as information pertinent to the National Contingency Plan requirements under the Fish and Wildlife Annex; not every item will be applicable to every situation.[20]

Introduction

This section generally should be completed in one, or possibly two paragraphs.

- General overview of the response strategy including: (1) a brief description - one to two sentences; (2) background, history, etc. as appropriate; (3) purpose of the response strategy; (4) identification of the species and designated critical habitat that may be affected (for consultations that will address large numbers of species, it may be desirable to present this list in the form of a table either attached or presented in another section. Also, if species that may potentially occur in the area are not included in this document, explain why).
  This should be developed jointly by the action agency and the Services.

Description of the Proposed Response Strategy

- Provide a description of the response strategy being considered. This is likely to be a detailed description taken substantially from the ACP. It should include how the

[19] It is not required that this planning template be formally written or completed during informal consultation, especially if no modifications to the strategy are required. However, it can be very useful in documenting the [team's] thought process for the administrative record, serving as a guide, or providing additional documentation as needed.

[20] The guide on "Developing Consensus Ecological Risk Assessments" provides procedures which may be helpful in exploring and analyzing these issues. Copies can be obtained from USCG Headquarters (G-MOR-2).

response action will be implemented, including equipment and methods. Examples include use of dispersants to avoid shoreline impacts, and deployment of booms to protect sensitive areas. Include all known aspects of the action, such as time frames, why the action is appropriate, indirect effects, etc. An example of an indirect effect may be hauling boom on, or driving vehicles through, a sensitive dune area to gain access to a spill site.
This should be developed by the action agency with the assistance of the Services.

- Provide a description of specific area that may be affected by the response strategy (i.e. Sample Bay, 100-mile section of outer coastline, etc.). Include some measure of the area potentially impacted (i.e., "This plan addresses oil spill response activities that may be conducted out two miles from the coast throughout the 100 mile coastline area encompassed by this ACP"). If different activities are being proposed in different areas, identify this. The team should discuss the appropriateness of presenting this information in terms of the activities that will be conducted within each area, or the areas where each activity will be conducted. For example, "Dispersants may be applied throughout the 10 mile coastline length of Area A and the 25 mile coastline length of Area B." Maps may be useful.
  This should be developed mainly by the action agency; however, modifications may be made with the assistance of the Services and subject to the approval process for chemical countermeasures in the NCP as appropriate.

- Identify how to quickly obtain species/habitat information during a spill (i.e. first refer to ACP and site summary sheet, call State FWS, check website, etc.).
  This should be developed jointly by the action agency and the Services.

- Identify emergency response points of contact to be notified during a spill. Establish spill parameters for notification as necessary. These should be included in emergency notification numbers as well as on any site summary sheets, in geographic response plans, etc.
  This should be developed jointly by the action agency and the Services.

Description of the Affected Environment

- Describe the listed species and designated critical habitat areas that may be affected by the action in terms of overall range and population status. Include the number and location of known subpopulations within and adjacent to the action area (i.e., identify the areas known to be used by the species and, if appropriate, identify the specific times periods of use, such as February - April). Discuss the action area in relation to the distribution of the entire population (e.g., edge of the range, center of population abundance, key reproductive area, etc.). Present views of Service recognized experts on the species, if appropriate.
  This should be provided by the Services.

- Ensure that these sensitive areas are referenced in the ACP (i.e. via ESI maps, specially generated GIS maps, site summary sheets, or other digitized format, etc.).
  This should be completed by the action agency.

- Provide biological data on listed species: historical use, presence, and potential use of habitat areas within the action area. Literature and other documents containing such information may be incorporated by reference. Provide species observation information, and recent results of species surveys, including, if appropriate, a description of methods, time of year surveys were performed, level of effort, and confidence intervals. Again, literature and other documents containing such information may be incorporated by reference. Maps may be useful to depict this information.
  The Services should assist in developing this information. In many instances the Services will be able to supply this information from their records.

- Identify other designated sensitive areas, both adjacent to and within the proposed action area. These include National Wildlife Refuges, National Marine Sanctuaries, etc.
  This should be developed jointly by the action agency and the Services.

Analysis of the Effects of the Action

- Describe all effects of the response strategy relative to the listed species of concern and its habitat, including designated critical habitat. This should include direct, indirect, beneficial, and cumulative effects as well as effects from interrelated and interdependent actions, if any.
  This should be developed jointly by the action agency and the Services.

- Describe any measures that may avoid or lessen adverse effects as well as any measures that will enhance the species' present condition. If appropriate, delineate the locations of such measures. A discussion of environmental "tradeoffs" (including no action) may be appropriate. For example, "Dispersants may be toxic to the listed aquatic species when used in concentrations above 70%; however, oil coming ashore and smothering the listed species in tidal marshes is of greater concern due to the extremely poor conservation status of this species." Reference any already completed relevant reports, studies, biological assessments, etc.
  This should be developed jointly by the action agency and the Services.

Modification to Strategy (as needed)

If necessary, after joint analysis of the information, the action or strategy may be modified.

- Describe the new strategy or action. For example, "Dispersants will not be used in

concentrations above X% or in areas less than three feet deep. They may be used in Area A and Area B. A Service representative from Regional field office B will be contacted during an oil spill response during the months of February - April in Area B."
This should be developed jointly by the action agency and the Services.

Documentation

This template is a guide to help you through the planning process, however, when sections are written out as the process is completed, the final document serves the same purpose as a biological assessment. It may be used to complete consultation pursuant to Section 7 of the ESA.

- The document should be maintained on file by the Services and may be referred to during an oil spill response.

- The Area Committee will ensure that this document becomes part of the ACP as appropriate such as:
- Included as an appendix to the Dispersant or In Situ Burn Operations Plan;
- Included as a reference document in the appropriate section of the ACP;
- Include relevant information in sections of the ACP such as Notifications, Site Summary Sheets, Geographic Response Plans, GIS maps, etc.

- The document should include points of contact from both the action agency and the Services.

APPENDIX D

SAMPLE POLLUTION REMOVAL FUND AUTHORIZATION (PRFA) LANGUAGE*

This Statement of Work (SOW) language is intended as sample language only. The language can be tailored to ensure that the FOSC is provided with the resources needed to meet the desired activities or functions required. Accordingly, more precise or succinct language may be used.

PRFA SOW additional/optional work elements to meet the FOSC's ESA mandated activities associated with removal actions:

…..

To arrange for, and as appropriate coordinate with, the resources needed to meet the conference and consultation requirements of the ESA.

Specific activities anticipated under this requirement include:

(a) Providing the expertise needed to make sensitive removal decisions which could potentially impact on listed species or critical habitats associated with this incident;
(b) Gathering and documenting the information needed to provide input into the aforementioned decisions and to document the resulting impact of removal actions; and
(c) As required, preparing the consultations required of the FOSC for the Service(s).

Funding under this agreement is provided for:

(a) Salaries, travel and per diem;
(b) Appropriate charges for use of equipment or facilities;
(c) Any actual expenses for goods and/or services reasonably obtained in order to provide the agreed upon support to the FOSC removal activities (including contracts.)

* Developed by the National Pollution Funds Center

APPENDIX E

SAMPLE LETTERS FOR REQUESTING CONCURRENCE OR FORMAL CONSULTATION

These sample letters have been developed to assist the Parties to this agreement in documenting the requirements of the Endangered Species Act. This is suggested wording only and may be used to complete the administrative record as needed. The request for concurrence can be used after the planning process for a particular area or countermeasure when it has been determined that no adverse effects will occur. The Services will provide a concurrence letter, as appropriate, for documentation. Alternatively, the request for formal consultation can be used after planning results indicate that adverse effects may still occur. If this is the case, the Services will evaluate the information developed jointly by the workgroup and issue a biological opinion.

Request for Concurrence Letter:

Mr./Ms. xxx
U.S. Fish and Wildlife Service/National Marine Fisheries Service
Division of Endangered Species

Dear Mr./Ms. xxx:

In accordance with the requirements of Section 7 of the Endangered Species Act, I am seeking your concurrence that the [Coast Guard's/EPA's] implementation of the [name of plan] is not likely to adversely affect the [identify the listed species and designated critical habitat that may be affected. Note, in cases where many listed species or critical habitat designations may be involved, it may be appropriate to refer to an attached list]. This [name of plan] has been developed with the assistance of [name of Service staff] of the U.S. Fish and Wildlife Service/National Marine Fisheries Service and in accordance with the procedures identified at 40 CFR Part 300, the National Contingency Plan. To assist in completing informal consultation, please find attached the Biological Evaluation that has been produced through the planning process described in the Inter-agency Memorandum of Agreement Regarding Oil Spill Planning and Response Activities Under the Federal Water Pollution Control Act's National Oil and Hazardous Substances Pollution Contingency Plan and the Endangered Species Act using the Planning Template contained in Appendix C of that Agreement.

Thank you for your efforts in this matter. If you require additional information, please contact [provide a contact with a telephone number].

Sincerely,

Request for formal consultation:

Mr./Ms. xxx:
U.S. Fish and Wildlife Service/National Marine Fisheries Service
Division of Endangered Species

Dear Mr./Ms. xxx:

In accordance with the requirements of Section 7 of the Endangered Species Act, I am requesting the initiation of Formal Consultation on the effects of the [Coast Guard's/EPA's] implementation of the [name of plan]. Through informal consultation with your staff [or identify the appropriate Service office(s)], we have determined that implementation of spill response activities in accordance with the subject [name of plan] is likely to result in adverse effects to [identify the listed species and designated critical habitat that may be affected. Note, in cases where many listed species or critical habitat designations may be involved, it may be appropriate to refer to an attached list]. This [name of plan] has been developed with the assistance of [name of Service staff] of the U.S. Fish and Wildlife Service/National Marine Fisheries Service and in accordance with the procedures identified at 40 CFR Part 300, the National Contingency Plan. While these actions may result in short-term adverse effects, it is our belief that the species [and designated critical habitat areas] will ultimately benefit from them. To assist in completing Formal Consultation, please find attached the Biological Evaluation that has been produced through the planning process described in the Inter-agency Memorandum of Agreement Regarding Oil Spill Planning and Response Activities Under the Federal Water Pollution Control Act's National Oil and Hazardous Substances Pollution Contingency Plan and the Endangered Species Act using the Planning Template contained in Appendix C of that Agreement.

Thank you for your efforts in this matter. If you require additional information, please contact [provide a contact with a telephone number].

Sincerely,

ESA Emergency Response Checklist

9717 ESA Emergency Response

[Link to ESA MOA Section 9716]

The FOSC notifies appropriate representatives of NOAA, USFWS, State Natural Resource Trustees and/or other agencies and stakeholders once an oil spill has occurred with the potential for impacting environmentally sensitive areas, endangered species and/or critical habitats. Actions of the FOSC:

- Use pre-identified points of contact or "Notification List" from ACP
- Gathers information about areas impacted, sensitive areas, species and critical habitats
    - As soon as possible after the spill has occurred, determine data needs and who will be providing or collecting the data
- Notify/alert Service representatives, NOAA SSC and/or DOI representative of any changes in response operations due to weather, extended operations or some other circumstance
- Obtain information from the USFWS or NMFS of seasonal variances (e.g. bird migration), or other natural occurrences affecting the resource
- Maintain a record of all written and oral communications during the response (See Appendix B of the ESA MOA for a means for tracking this information), to include recommended response procedures and incidental take.
- If listed species or critical habitats are impacted or could be present in the area affected by response activities, initiate emergency consultation by contacting the USFWS and NMFS through agreed-upon procedures.
- Appoint an Endangered Species expert who will serve in the Incident Command System (ICS) command structure to help ensure that the necessary information, using terminology understood by USFWS and NMFS, is gathered at the Incident Command Post (ICP) daily
    - If appropriate, the NOAA SSC and/or the USFWS representative may coordinate endangered species expertise for the FOSC
    - If there is no USFWS or NMFS representative in the ICS, but they are aware of the situation, the FOSC must ensure that the NOAA SSC and/or DOI are apprised of the situation
    - Information gathered will be used in the consultation
- The Incident Action Plan will serve as formal documentation of actions directed to minimize the impacts of response actions
- Emergency consultation continues until the FOSC determines that the spill response is complete.

USFWS and/or NMFS provide the FOSC with timely recommendations to avoid and/or minimize impacts to listed species and critical habitat. If an incidental take is anticipated, USFWS and/or NMFS would advise FOSC of ways to minimize this, or, if this is not possible, document the actual take of listed species.

A "***take*** is defined in the ESA as: "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." The USFWS has defined "harm" as "an act which actually kills or injures wildlife." 50 C.F.R. § 17.3. The regulation further explains that "[s]uch act may include significant habitat modification where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering."

The FOSC should request the support of a USFWS and/or NMFS representatives (or someone else mutually agreed upon) to gather and document the information necessary for post-emergency Formal Consultation, including:

- Description of the emergency (the oil spill response)
- Evaluation of the emergency response actions and their impacts on listed species and their habitats, including documentation of how USFWS and/or NMFS recommendations were implemented, and the results of implementation in minimizing take
- Comparison of the emergency response actions with the pre-planned countermeasures and information in the ACP

Note: As necessary, the FOSC can make funding available to USFWS and/or NMFS for costs incurred in providing any agreed upon assistance such as preparing the Biological Assessment for formal consultation. However, the USFWS and/or NMFS are not reimbursed for completing a Biological Opinion.

ESA Post Response

Checklist

9719 ESA Post-Response

The FOSC determines when removal operations are complete and closes the case ensuring that:

- Lessons learned are recorded;
- Documentation is filed; and,
- Area Committee is advised of any necessary changes to the ACP

The Emergency Consultation Checklist from the ESA MOA [Link to ESA MOA 9716] should be compiled before the FOSC determines that the response operations are completed and the case is closed. Oil Spill Liability Trust Fund (OSLTF) funding is not available after the case is closed.

The FOSC, USFWS and NMFS jointly evaluate the impacts of response activities on listed species and critical habitat. The information for the evaluation comes from data gathered during the response, not from any new studies.

If joint evaluation concludes that listed species and/or critical habitat were not adversely affected by response activities, the consultation process is complete.

The FOSC must send a letter to USFWS and/or NMFS including:

- Report of this agreement; and,
- Request a letter of concurrence from USFWS and/or NMFS.

If joint evaluation results in a disagreement between USFWS, NMFS, and the FOSC, USFWS and/or NMFS will send the FOSC a letter stating why they believe there were adverse effects on listed species or critical habitat. The FOSC may act on the USFWS/NMFS reply or simply document the response.

If impacts have occurred, the FOSC sends a letter to USFWS and/or NMFS to initiate *Formal Consultation*. Enclose the information gathered during the response with any modifications that may have been made during the post-response joint evaluation.

- This can be done by finalizing the Emergency Consultation Checklist from Appendix B of the MOA and submitting it with a cover letter and a request for formal consultation from Appendix E as an initiation package to the Service(s).
- Also see Activity 11: Documenting the Risk Assessment, pg. 65 of the Guidebook.

Note: If a USFWS representative assists in preparing the initiation package, the same representative will not be responsible for reviewing it.

The USFWS and/or NMFS have 30 days from receipt of the initiation package to determine if the package is complete. When complete, they issue a Biological Opinion within 135 days.

Example Of Informal Consultation Letter From USFWS to the Response Organization

9735 Informal Consultation

Memorandum

December 9, 2004

To: Operations Section Chief (O'Brien's Group)
Deputy Operations Section Chief (USGC)
Planning Section Chief (O'Brien's Group)
Deputy Planning Section Chief (USCG)

From: Group Supervisor, Wildlife Recovery

Subject: Practices for minimizing impacts to bald eagles during response actions related to the ***M/V Athos I*** discharge of oil – informal consultation pursuant to Section 7 of the Endangered Species Act.

Since the inception of ***M/V Athos I*** response (Incident) activities and pursuant to Section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*), a representative of the U.S. Fish & Wildlife Service (Service), acting as Wildlife Recovery Group Supervisor, has verbally coordinated with the Operations Section and U.S. Coast Guard to tender recommendations to minimize or avoid adverse impacts to bald eagles due to response actions related to the Incident. Those recommendations are consistent with the response strategies outlined in the Philadelphia Area Contingency Plan including:

- Recover mobile oil;
- Recover oiled wildlife – both dead and alive to prevent scavenging and secondary contamination;
- Boom creeks to prevent oiling of sensitive areas, especially eagle foraging areas; and,
- Monitor shorelines for oil impacts, and coordinate the selection of cleanup methods with the Environmental Unit.

Further, the Service recommended that:

- Response-related aircraft maintain a ¼ mile radial distance and 500 foot altitude from nest areas during aerial surveys; and,
- Areas identified by the Service as eagle foraging habitat should receive the highest priority for shoreline cleanup. The Service, as part of the Incident Operations Center, wants to review cleanup methodologies used in those areas prior to implementation. Cleanup methods selected should use the least amount of personnel for maximum cleanup effect, and media coverage around eagle foraging area should be avoided.

The Wildlife Recovery Group Supervisor (FRC Stern) coordinated with the Endangered Species Biologists at the Service's New Jersey Field Office on Monday, 29 November 2004 and Wednesday, 9 December 2004 to review the aforementioned recommendations and develop additional recommendations as appropriate. The Service as part of the response action has and continues to coordinate with Biologists from the New Jersey Division of Fish and Wildlife – Endangered, Non-game Species Program (ENSP) who are currently monitoring eagles in the vicinity of the Incident. ENSP Biologists are placing deer carcasses out to distract bald eagles from potentially scavenging on oiled wildlife. The Service recommends that use of deer

carcasses to distract bald eagles be continued as part of the Incident Action Plan in coordination with ENSP. Additionally, the Wildlife Recovery Group Supervisor has coordinated with the Tri-State Bird Rescue and Research veterinarian Dr. Erica Miller on Monday 29 November 2004 regarding potential concerns for bald eagle health issue in the event of oiling.

The Service further recommends that the U.S. Coast Guard continue to coordinate oil recovery and selection of shoreline cleanup methodologies with the Service during evolution of the Incident. If you have further questions, please contact the Wildlife Group Supervisor or Ms. Lisa Arroyo of the Service's New Jersey Field Office at 609/646-9310.

Wildlife (Bird) Recovery Options

9739 Wildlife (Bird) Recovery Operations/Procedures

Capture of birds will only be attempted by qualified personnel with USFWS oversight. Oiled wildlife are highly unpredictable and can inflict serious injuries to a responder; accordingly, proper personal protective equipment shall be used when capturing or handling oiled wildlife. In some cases, The USFWS may recommend that the FOSC seek the assistance of the USDA APHIS - Wildlife Services to help with wildlife recovery operations. Safety must be accorded the highest priority throughout the capture and transport process. Migratory birds are susceptible to stress; handling, noise and visual stress should be minimized.

Teamwork is essential in capture operations. As they lose their waterproofing, oiled birds move to shore, first preening on open beaches and river banks and later hiding under cover. Birds in this condition can be retrieved in teams of two or three people on foot with radio communication approaching quietly from water's edge and blocking access to water. This technique is most effective before dawn. Birds can then be captured using long-handled dip nets, towels, or picked up by hand. Birds should never be chased to exhaustion.

Certain birds may be baited in close by "chumming" with fish or squid and captured with a long-handled net. Several species may also be effectively captured from a boat with a netgun within 10-15 meter range. Cannon, rocket and drop nets may be effective, when used with baiting techniques. Swim or walk-in traps may also prove effective, but must be regularly monitored.

Recovery Processing

Once birds are captured they should be removed from the netting and placed in towels, sheets or netting over the entire bird. Wings must be folded normally against the body. Care must be taken to avoid the bills and talons of large birds such as herons and raptors. A reverse body hold is recommended for large birds. Always hold the bird below waist level and away from the face. Always carefully handle the birds to minimize damage to feathers.

Each captured bird should be accompanied by a form with the following information: capture boat and personnel; date, time and location of capture; technique used to capture the animal; amount of oil in the area and whether the bird was observed or captured in the oil; behavior at capture, e.g., aggressive, lethargic, comatose; and, description of the bird, i.e., sex, age, distinguishing marks.

After transport, birds should be immediately examined by an attending veterinarian or other qualified personnel. If a treatment center is not in close proximity, it may be necessary to perform initial treatment at the collection site, such as clearing mouth and nostrils of oil; rehydrating the bird; checking for signs of oil toxicity, pining a cloth around the birds body to prevent hypothermia; and placing the bird into a transport container and avoiding disturbance, except to hydrate.

Carcass Retrieval and Processing

For all spills, a primary response goal is to prevent continued or additional contamination of wildlife as a result of predation. All bird carcasses should be retrieved and delivered to collection or morgue sites directed by the USFWS personnel to prevent oil from entering the food chain. Each carcass should be accompanied by a form containing the date and place of collection, the name of the collector, and if known, the species collected. Forms accompanying the carcass should be kept in a plastic storage bag for protection. An indelible pen or pencil should be used for labeling. If the carcass is not collected, a form should still be filled out and submitted to the USFWS collection or morgue site including a brief explanation for not collecting the specimen. Place retrieved carcasses in a plastic bag, ***one carcass per bag only***. Place the completed retrieval information form in a zip-lock bag, place it in the bag with the carcass, and tie the plastic bag shut for delivery to the Wildlife Recovery Area / morgue. Carcasses should be kept cool, but not frozen during transport to the morgue.

Environmentally Sensitive Area (ESA) & Essential Fish Habitat (EFH) Post Response Procedures

Endangered Species Act (ESA) and Essential Fish Habitat (EFH)
Post-Response Procedures

The purpose of this document is to inform the Federal On-Scene Coordinator (FOSC) of the potential need to conduct consultations **after** the emergency response phase of an incident is over, though every effort should be made to engage the Services early on concerning potential or actual response actions. During the course of emergency response operations, an FOSC must document and track environmental compliance implementation procedures regarding ESA Section 7 and EFH including, but not limited to: Incident Command System (ICS) Form 232-CG Resources at Risk Summary reports, Incident Briefing Form (ICS 201), ESA/EFH Emergency Consultation checklists, etc. The FOSC must comply with consultation requirements for ESA Section 7 and EFH pursuant to 50 Code of Federal Regulations (CFR) § 402.05 and 50 CFR § 600.920.

During a response, the FOSC is responsible for directing response actions so that ESA listed species are not put at risk, or that formally designated Critical Habitats of ESA listed species and/or EFHs are not destroyed. This process is accomplished through pre-spill planning consultations, along with documenting the results of those consultations within Regional Contingency Plans and Area Contingency Plans, as appropriate. However, spill response remains incredibly dynamic and not all federal actions and impacts can be appropriately planned for. For actions not covered by a pre-spill consultation that are used, or are considered for use during an emergency response, the FOSC must follow ESA and/or EFH emergency response procedures and complete ESA and/or EFH consultations in collaboration with the Services once the emergency phase of the response has ended.

There are three criteria for evaluating the effects of response actions on ESA listed species and designated Critical Habitats, and two criteria for evaluating the effects of response actions on EFH. These criteria are used by the FOSC to determine the type of ESA consultation required with National Marine Fisheries Service (NMFS) and/or U.S. Fish and Wildlife Service (USFWS), and/or type of EFH consultation required with NMFS. Depending on the incident response, the FOSC may coordinate with the National Oceanic and Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC), Department of the Interior (DOI) representative, subject matter experts, and/or the Services to determine whether response actions had one of the following effects.

For ESA listed species and designated Critical Habitats:

(1) The action had **No Effect** (none at all, negative or positive);

(2) The action **May Affect**, but was **Not Likely to Adversely Affect (NLAA)**, listed species or adversely modify or destroy designated Critical Habitat; or

(3) The action **May Affect,** and was **Likely to Adversely Affect (LAA)**, listed species and likely adversely modified or destroyed designated Critical Habitat.

For EFH:

(1) The action had **No Adverse Effect**; or

(2) The action **May Adversely Affect** (**Adverse Effects** are anything that changes the quality or quantity of EFH).

"No effect" or "no adverse effect" is the appropriate determination if the response actions occurred in an area where no ESA listed species and designated Critical Habitats occur and no EFH is present, or

if the action and the stressors of that action would not affect ESA listed species, designated Critical Habitats, or EFH. To assist with "no effect" determinations, the FOSC should ask whether ESA listed species or designated Critical Habitats were exposed to the action or the effects of the action. If not, then "no effect" is the appropriate determination. For example, if there is a seasonality to the presence of an ESA listed species, and the action occurs within the season where the species is not present during the time of response actions, then a "no effect" determination is acceptable. An example of this is nesting loggerhead sea turtles in the Gulf of Mexico. If shoreline cleanup is to occur at the time when there are no nests and no nesting activity, then the action would have no effect on loggerheads. However, it is important to check whether other sea turtle species may be nesting in the area. This "no effect" determination must be documented within the respective unit's administrative record. Similarly, if the "no adverse effects" on EFH determination is made, this should also be documented.

If the FOSC determines that emergency response actions "may affect" ESA listed species and/or designated Critical Habitat—that is, species or designated Critical Habitats are likely to be exposed to the response actions—then the FOSC shall follow the consultation processes identified in 50 CFR § 402 during and following the emergency operations.

If the FOSC has made a "may affect" determination during an emergency response, the FOSC must engage in emergency consultation with USFWS and/or NMFS as soon as practicable. This engagement with the Services during the response will likely aid in reducing the likelihood of adverse effects on listed species and/or designated Critical Habitats and should help the FOSC meet their responsibility to engage in the post-response consultation once the response has ended. In accordance with the 2001 Memorandum of Agreement (MOA), these consultations shall remain active until the conclusion of emergency response operations.

Pursuant to 50 CFR § 402.14(c), the FOSC must submit a written request to the Services once the emergency response phase is over. The type of consultation and request to the Service(s) will depend upon the type of effects the response actions had on listed species and/or designated Critical Habitat. If the FOSC determines that the response actions were NLAA (***informal consultation***), the FOSC must then submit a letter to the Service(s) with the details below, their determination, and request concurrence on that NLAA determination. If the FOSC determines that the response actions were LAA, the FOSC must submit an initiation package (and/or Biological Evaluation) to begin ***formal consultation*** after the emergency phase of the response is over. This process is necessary to document and evaluate any adverse effects that may have occurred as a result of response actions. The FOSC cannot make a determination on jeopardy or adverse modification of critical habitat, this is the responsibility of the Services. Therefore, the FOSC must work with the Services to evaluate response actions determined LAA (by the FOSC), and if those response actions resulted in jeopardy or adverse modification of critical habitat. Due to the nature of emergency consultation, determinations of jeopardy or adverse modification of critical habitat are challenging to evaluate during a response. However, any recommendations provided by the Services during the response and the consultation, after the fact, must be documented in the resulting emergency BO and can be integrated into future response actions and response plans.

The following information must be provided to the Services in order to begin an informal or formal consultation:

(1) A description of the agency response action(s) taken;

(2) A description of the specific area that may have been affected by response actions to include listed species and designated Critical Habitat;

(3) A description of Best Management Practices (BMPs)[1] that were followed, if applicable;

(4) A description of the manner in which any ESA listed species or designated Critical Habitat may have been affected by the response action, and an analysis of any cumulative effect;

(5) Any relevant reports, including environmental impact statements, environmental assessments, or biological evaluations prepared, if applicable; and

(6) Any other relevant available information on the response action, listed species, or designated Critical Habitat.

Informal consultations conclude with a Letter of Concurrence from the Service(s). Formal consultations conclude with a Biological Opinion (BO) from the Service(s). For examples of template letters, BOs, or any additional ESA Section 7 templates or document, please refer to NRT.org[2]

RRT3 Environmental Best Management Practices for Coastal Zone Oil Spill Response

(DEC 2023)

REGIONAL RESPONSE TEAM III (RRT3)

Environmental Best Management Practices (BMPs) for Oil Spill Response in Regional Response Team 3 (RRT3) Coastal Zone

BMPs for Oil Spill Response

Appendix 9-A6

December 2023.0

RECORD OF CHANGES

The Regional Response Team III (RRT3) Executive Committee approved the RRT3 Environmental Best Management Practices (BMPs) for Coastal Zone Oil Spill Response on December 6, 2023. Maintenance of this plan is the responsibility of the RRT3 Consultation, Natural Resources, and Damage Assessment (CNRDA) Workgroup. Minor changes may be made periodically, and an update and review will be conducted at least once per year, at a minimum, to validate points of contact. The most current version of the plan will be posted on the RRT3 Website under the Regional Contingency Plan (RCP) Appendix 9 and the USCG District 5 District Response Advisory Team (D5 DRAT) Sharepoint site.

USE OF THE ENVIRONMENTAL BMPS FOR OIL SPILL RESPONSE IN THE COASTAL ZONE

Regional Response Team III (RRT3) is committed to implementing measures to reduce and avoid potential impacts on federally listed and managed species, designated critical habitat, Essential Fish Habitat (EFH), and cultural/historical resources. The RRT3 has compiled the following collection of Best Management Practices (BMPs) to avoid and/or minimize impacts to trust resources under the Marine Mammal Protection Act (MMPA) and Migratory Bird Treaty Act (MBTA), to serve as recommendations under the Endangered Species Act (ESA) Section 7 consultation regulations to avoid and minimize effects to endangered and threatened species and critical habitat, to minimize and avoid adverse effects on identified categories of EFH under the Magnuson-Stevens Fishery Conservation and Management Act (MSA), and to avoid and minimize effects to cultural and historic resources under the National Historic Preservation Act (NHPA) Section 106.

Background and Purpose

The purpose of this document is to provide recommendations and guidance to the Federal On-Scene Coordinator (FOSC) to avoid and minimize impact to fish, wildlife, and cultural/historic resources during a response to an oil spill.

All BMPs are provided as recommendations and guidance, developed in coordination with Department of Commerce National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS), and U.S. Department of the Interior's (DOI) U.S. Fish and Wildlife Service (USFWS), to avoid and minimize impact to fish and wildlife resources during a response to an oil spill. These agencies are referred to as "the Services." State Historic Preservation Office (SHPO) input for cultural/historic resource considerations during oil spill response operations is also included within this guidance document.

This document is not intended to cover all possible scenarios or every individual species. The BMPs provided in this document are general in nature for oil spill response actions and enable the FOSC to quickly implement BMPs for response actions at the onset of a response. Due to area, environmental, and situational differences amongst potential operation areas, the RRT3 maintains this list of BMPs as an appendix to the Regional Contingency Plan and will update and revise the list as additional BMPs are developed, and/or updated information becomes available regarding the effectiveness and feasibility of implementing the BMPs. Incident specific BMPs may need to be developed to account for incident specific variances based on spilled products, species or location specific concerns, and types of response actions utilized and/or considered.

Direction to USCG Fifth District Units

The U.S. Coast Guard (USCG) Fifth District units will take these BMPs into consideration when carrying out oil spill response operations. This guidance will be used to cover oil spill and/or hazardous substance response actions within the Fifth Coast Guard District coastal zone, which includes Delaware, District of Colombia, Maryland, portions of New Jersey, North Carolina, portions of Pennsylvania, and Virginia.

The regional NOAA SSC and/or DOI Regional Environmental Officer **shall** be informed whenever the FOSC engages in emergency consultation with the Services. The SHPO **shall** be notified for NHPA consultations.

U. S. Coast Guard (USCG) District Incident Management and Preparedness Advisors (IMPAs) and District Response Advisory Teams (DRATs) are excellent resources to consult with regarding application of BMPs.

The USCG IMPA and DRAT are available 24/7 via District Command Centers.

Note: *This is a guidance document only. Units are encouraged to suggest modifications to this document to the RRT3's Consultation, Natural Resources, and Damage Assessment (CNRDA) Workgroup.*

ENVIRONMENTAL BMPS FOR COASTAL OIL SPILL RESPONSE

General Response Operations

☐ Response personnel may not attempt to scare, herd, disturb, or harass any protected species to encourage them to leave the area. Coordination with National Oceanic and Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC), U.S. Fish and Wildlife Service (USFWS) and/or National Marine Fisheries Service (NMFS) Stranding Coordinator, or appointed point of contact, may result in authorization for these actions.

☐ Report stranded, injured, sick, trapped, entangled, or dead wildlife to the Incident Commander (IC) and Environmental Unit as soon as possible to ensure appropriate agency notifications are made. *Utilize the 'USFWS Wildlife Spill Response Survey' within the Survey123 app if available and being utilized for incident* ArcGIS Survey123 Downloads (esri.com)*.The USFWS species are preloaded into the Wildlife Spill Response Survey, however any species including NMFS species can be recorded in the app.*

☐ If a sea turtle is stranded, injured, or sick, and actively moving, it should be retained onboard a vessel or if on land, responders should remain with the turtle until the stranding/rehabilitation personnel provide guidance on what action should be taken, which could include transferring the turtle to a designated stranding/rehabilitation facility.

☐ If a sea turtle is stranded, injured, or sick but unresponsive (doesn't move its head or flippers when handled), you should follow the handling and resuscitation guidelines after you have called the NOAA hotline at 866-755-NOAA (6622). Do not assume that an inactive turtle is dead. The onset of rigor mortis and/or rotting flesh are often the only definite indications that a turtle is dead. Releasing an unresponsive turtle into any amount of water may drown it. Unresponsive sea turtles may recover following resuscitation.

- For your and the turtle's safety, always pick it up by the shell and keep your hands away from the head. Sea turtles have been known to revive up to 24 hours after resuscitation procedures have been followed. In accordance with Sea Turtle Resuscitation Regulations (50 CFR 223.206(d)(1)), steps for resuscitation can be found at https://media.fisheries.noaa.gov/dam-migration/sea_turtle_handling_and_resuscitation_measures.pdf.

☐ Handling live sturgeon should be minimized and used only when necessary. Sturgeon should be supported by a sling or net when being moved. Live sturgeon must never be held vertically by the tail or gills and should never be tied by the tail. Sturgeon should be kept in water to the maximum extent possible to reduce stress.

- For a non-responsive or overly stressed sturgeon, personnel must allow the animal to recover in floating net pens or in well-aerated onboard live tanks and shielded from direct sunlight. Alternatively, the sturgeon may be immersed in clean river water and moved back and forth to aid water passage over the gills.
- The sturgeon should be released as soon as possible when it has recovered. At water temperatures <7°C (44°F) and >27°C (80°F), holding time of a recovered sturgeon must not be greater than 30 minutes. A spotter should watch the fish as it is released making sure it stays submerged and does not need additional recovery immediately after release.
- Sturgeon are extremely sensitive to chlorine and other sanitizing solutions. Use care when using any of these products around sturgeon.

☐ If any impacted sea turtle, sturgeon, or marine mammal (or their parts) are observed, NMFS should be contacted for collection protocols. If a Wildlife Branch is stood up, coordination for response and collection should be communicated through the NMFS representative in the Wildlife Branch. NMFS may authorize collection by spill response personnel if species specific responders are not available (and delegation authority is allowed under the appropriate permit) and will provide instructions on proper handling and disposition. For impacted marine mammals and sea turtles, call the NMFS Regional Marine Animal Hotline: 866-755-NOAA (6622), Option zero to speak with NMFS staff. For sturgeon, reports should be made to NMFS Protected Resources Division by phone (978-281-9328) and e-mail (nmfs.gar-sturgeon-salvage@noaa.gov) as soon as possible.

- Do not dispose of any federal trust resource marine mammal or turtle parts until examination and documentation is conducted. Disposal will not take place until federal trustees (NOAA/USFWS) give final approval.
- Wildlife operations present some unique challenges to evidence handling requirements that often must be resolved early in response. Important data and samples are collected during oil spill response that ultimately may be used to assess exposure of species to oil and injuries resulting from that exposure. This information and material ultimately may be used for legal purposes including both criminal and civil proceedings. The potential for litigation associated with an oil spill requires specific measures when collecting, handling, and transferring samples and data. Coordinate with federal trustees (NOAA General Counsel's Office and the DOI Office of the Solicitor) to ensure chain of custody (CoC) protocols are followed. The CoC record should include the names of sample collectors, sample identification numbers, date and time of sample collection, location of sample collection, and names and signatures of all persons handling the sample in the field and in the laboratory. The documents provided below provide chain of custody information:
    - Guidelines for Oil Spill Response and Natural Resource Damage Assessment: Sea Turtles at https://media.fisheries.noaa.gov/dam-migration/opr-61_final.pdf.
    - NOAA Pinniped and Cetacean Oil Spill Response Guidelines at https://repository.library.noaa.gov/view/noaa/10479.
    - Additional chain of custody forms for other NOAA resources can be found at https://www.diver.orr.noaa.gov/field-forms-and-templates.

☐ Human Safety Considerations:

- Prior planning, training, and protective equipment should be provided for responders that may need to engage directly with marine mammals.
- Zoonotic pathogens are another risk of handling marine mammals.
- Safety perimeters around pinniped colonies should be established.

Vessel Operations

☐ All response vessel operators and crew must watch for and avoid collision with species protected under the ESA and MMPA (sea turtles, manatees, seals, dolphins, whales, Atlantic and short-nose sturgeon). The Environmental Unit can provide an updated list of protected species in the response area. When available a dedicated wildlife observer should be assigned for each response area.

☐ All response vessels shall maintain minimum distances specified below for specific species:

- 1,500-ft distance (500 yards) from North Atlantic right whale.
- 300-ft, as practicable, from all other marine mammals (i.e., dolphins, other whales, seals/pinnipeds, and porpoises):
  - Seal colonies will likely flush (i.e., move away from) from haul outs into the water at greater distances than 300-ft. Consideration should be given to the potential presence of pups on haul outs in certain seasons. A biologist associated with an authorized marine mammal stranding response program experienced in marine mammal/protected species identification should be onboard to advise location of boom deployment distances when possible.
- 300-ft from waterfowl /seabird aggregation sites. Large numbers of sea birds and waterfowl winter in coastal waters bays and tributaries, with flocks of up to 5,000 individuals. Boat operations must maintain a minimum distance from waterfowl / sea bird aggregation sites.
- 150-ft from sea turtles.
- 50-ft from manatees (rare in RRT3). All in-water operations, including vessels, must be shut down if a manatee comes within 50 ft of the operation. Activities will not resume until the manatee(s) has moved beyond the 50-ft radius of the project operation, or until 30 minutes elapses if the manatee(s) has not reappeared within 50 ft of the operation. All on-site project personnel are responsible for observing water-related activities for the presence of manatees. Animals must not be herded away or harassed into leaving.
- 100-ft from all other protected species not already listed above. Stop operating mechanical equipment, including response vessels, immediately if any protected species is observed within a 100-ft radius and resume after the species has departed the area of its own volition.

☐ All response vessels should:

- If marine mammals, sea turtles, or bird colonies are observed within the response area, report to Environmental unit via Wildlife Hotline and/or USFWS Wildlife Spill Response Survey in Survey123 (if established). If Environmental Unit is not yet established, report to the Operations Section. If there is the potential for damage to marine resources, it is recommended that an Environmental Unit be established. Reports should be submitted by the end of the current operational period.
- When sea turtles, dolphins, or whales are sighted while the vessel is underway (e.g., bow-riding), attempt to remain parallel to the animal's course. Avoid excessive speed or abrupt changes in direction until they have left the area.
- Report if a whale is observed within the envelope of the NOAA spill trajectory for the next 48 hours.

- Any vessel collisions with and/or injury or impacts to any protected species (sea turtles, manatees, dolphins, whales, etc.) shall be reported to the Wildlife Hotline immediately. Likewise, report any stranded, injured, trapped, entangled, or dead protected species to the Wildlife Hotline as soon as possible for further guidance on what action should be taken.
- Mariners shall check various communication media for general information regarding avoiding ship strikes and specific information regarding North Atlantic right whale sightings in the area.
  - Vessels 65 ft in length or longer must comply with the Right Whale Ship Strike Reduction Rule (50 CFR 224.105), which includes reducing speeds to 10 knots or less in Seasonal Management Areas.
    - Reduce speed to 10 knots or less when a right whale sighting is reported, mother/calf pairs, or groups of marine mammals are observed, when safety permits.
    - Secure all materials on vessels to prevent inadvertent loss overboard.

☐ All response vessels will follow marked channels and/or routes using the maximum water depth whenever possible.

☐ All response vessels shall operate at "Idle Speed/No Wake" at all times while in water depths where the draft of the vessel provides less than a 4-ft clearance from the bottom, and after a protected species has been observed in and has departed the area or adjacent to sensitive/environmentally important shorelines.

☐ Avoid vessel grounding, prop and bow/keel/skeg scarring, and prop washing in tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties.

☐ Avoid/minimize anchoring and spudding on tidal marsh, seagrass, and oyster reef habitats; anchor and spud on bare sand and mud bottoms, while avoiding archaeological sites or other historic properties. As soon as practically possible, consult with the State Historic Preservation Office (SHPO) and Tribal Historic Preservation Office (THPO) to determine proximity of archeological/historic sites and specific best management practices for those areas.

☐ Avoid/minimize shading of seagrasses with large vessels and barges for more than a few days; move large vessels and barges from over seagrasses onto bare sand or mud substrates when not undergoing active operations (such as in barge staging areas).

☐ Where equipment or crews must gain access across tidal marsh, seagrass, or oyster habitats, use shallow draft vessels to minimize disturbance, as applicable.

☐ Identify pinniped colonies in the response area as soon as possible and avoid disrupting the group as much as can be reasonably achieved. A response vessel should have a biologist experienced in marine mammal/protected species identification to observe and direct the response team to minimize impacts to groups of seals.

☐ If manatees are present, all water-based work and vessel operations must be in accordance with USFWS Standard Manatee Conditions for In-Water Activities (fws.gov). All response personnel shall be instructed about the presence of manatees and the need to avoid collisions with and injury to manatees. Advise all response personnel that there are civil and criminal penalties for harming, harassing, or killing manatees. Notify USFWS if manatees are observed.

On-water Mechanical Operations

(On-water Containment, Recovery, Protection)

☐ A biologist experienced in marine mammal/protected species identification or dedicated crew member is required for all skimming, booming, burning, and dispersant operations, with responsibility for avoiding marine mammals, sea turtles, birds, and reporting distressed or deceased animals.

☐ Stop operating mechanical equipment, including response vessels, immediately if a protected species is observed within a 50-ft radius and resume after the species has departed the area of its own volition.

☐ Entanglement:

- All in-water equipment (including hard and sorbent booms) must be properly secured with materials that reduce the risk of entanglement of marine species. Booms, lines, and other equipment must be made of materials that reduce the risk of entanglement of marine species. Keep all in-water lines (rope, chain and cable, including the lines to secure boom, buoys, anchors, etc.) stiff, taut, and non-looping. Floating line should be used as appropriate.
- Where feasible, the use of equipment with breakaway capabilities is advised to prevent or minimize the risk of entanglement of marine species.
- The Sea Turtle Stranding and Salvage Network (STSSN) should be contacted if sea turtles are entangled or entrapped during offshore operations.

☐ Entrapment:

- In-water equipment (including hard and sorbent boom) must be placed in a manner that does not entrap species within the work area or block access for them to navigate around the work area.
- If protected species become entrapped in an enclosed area, notify NMFS immediately. If observers note entrapped animals are visually disturbed, stressed, or their health is compromised, then activities may cease so the animal can either leave on its own or be moved under the direction of NMFS.
- The Sea Turtle Stranding and Salvage Network (STSSN) should be contacted if sea turtles are entangled or entrapped during offshore operations.

On-water Chemical Countermeasures

(Dispersants, Solidifiers, Herding Agents, Elasticity Modifiers)

☐ A biologist experienced in marine mammal/protected species identification or dedicated crew member is required for all skimming, booming, burning, and dispersant operations, with responsibility for avoiding marine mammals, sea turtles, birds, and reporting distressed or deceased animals.

☐ Where approved, dispersants should not be used within a 3-nautical mile radius of marine mammal species (e.g., whales, dolphins, seals, sealions, and manatees). The radius should increase to 10-nautical miles if North Atlantic right whales are observed in the area.

☐ Where approved, avoid dispersant applications near bird concentration areas and minimize bird exposure from wind drift of applied dispersant.

Other Countermeasures

(In-situ Burn, Bioremediation)

- ☐ A biologist experienced in marine mammal/protected species identification or dedicated crew member is required for all skimming, booming, burning, and dispersant operations, with responsibility for avoiding marine mammals, sea turtles, birds, and reporting distressed or deceased animals.
- ☐ Watch for and avoid marine mammals while operating vessels or aircraft involved directly or in support of in-situ burn operations. Marine species observers on the ignition vessel will monitor 3 areas prior to the burn (the area in front of the tow boats, oil concentrated in the boom, and any oil trailing behind the boom). A survey should be conducted in the burn area after the burn is complete and any distressed or dead marine mammals should be counted and reported to the Environmental Unit immediately.
- ☐ Avoid burning near bird concentration areas and minimize bird exposure from wind drift of smoke.
- ☐ Avoid burning near archaeological sites or other historic properties, particularly when these are not completely submerged.

Aircraft Operations

(Airplanes, Helicopters, Drones/Unmanned Aircraft Systems)

☐ Prior to operating Unmanned Aircraft Systems (UAS) coordinate with respective land managers to get specific UAS limitations.

☐ UAS flights should be limited to 100 feet above ground level (AGL) above resting birds on land or water (i.e., not in flight). Rotary aircraft should limit elevations to 300-400 feet AGL. If hazing/disturbances occur, increase altitude and report adjusted height to the Environmental Unit.

☐ Fixed-wing aircraft should follow NOAA marine mammal aerial survey protocols for speed (100 mph preferred), height (1000 feet AGL), and dwell time and for aircraft choice.

- For flyovers for identifying animals in the area are best done from aircraft that can fly low and slow and remain in an area for an extended period.

☐ Aircraft must stay >1,000 feet above bird nesting and aggregation sites and limit repetitive passes to minimize disturbance.

☐ Where deemed applicable, wildlife observers may be deployed on aircraft to report and record sightings of ESA species and/or other wildlife.

Vehicle Operations

(All-Terrain Vehicles, Automobiles/Trucks Heavy Equipment)

- ☐ Prior to vehicle operations, a biologist experienced in shorebird species identification is required to evaluate beaches for use by shorebirds (nesting, fledgling) each day.
- ☐ Prior to vehicle operations, the SHPO and THPO (if applicable) should be consulted to avoid disturbance of archaeological sites or other historic properties.
- ☐ Generally, preference is given to operations during daytime periods to minimize impacts to sea turtles and nesting shorebirds. Prior to any nighttime operations, it is highly recommended to consult with the Services for guidance.
- ☐ Utilize a lightweight vehicle with low tire pressure (10 psi), such as an All-Terrain Vehicle (ATV) or Mule whenever possible to reduce sand compaction and/or rutting.
- ☐ Utilize the same trackline for vehicle operations to minimize disturbance to multiple areas.
- ☐ Power wash vehicles prior to operating on beach areas to prevent spread of invasive species (e.g., Asian sand sedge).
- ☐ Enter the beach only at designated access points and proceed directly to the hard-packed sand near or below the high tide line. Stay below the tide line when driving if no oil is present and it is safe to do so.
- ☐ Do not drive in dune habitat.
- ☐ Avoid driving over the wrack line or areas of dense sargassum (otherwise known as seaweed), which may contain sea turtle hatchlings or newly hatched birds.
- ☐ Do not enter posted sea turtle or shorebird nest sites and minimize time spent around these sites. Most of these will be marked with posts and signs, but not all.
- ☐ Drive slowly. Travel should be slow enough to observe any bird eggs, chicks, or sea turtle hatchlings in the vehicle's line of travel. Be aware that bird chicks often feed along the water's edge. They may freeze in place rather than run away when ATVs or other vehicles approach.
- ☐ Check under and around vehicles and heavy equipment parked in shoreline areas before they are moved. Shorebirds (piping plover and red knot) are especially vulnerable when they are roosting at night, and extra care should be taken at these times. However, by this time of year, it is likely that these two federally threatened shorebird species have departed the area.

Shoreline Response Operations

(Protection/Containment: Pre-impact Debris Removal, Deflection/Protection Boom, Barriers/Berms, Flooding; Shoreline Treatment / Cleanup: Natural Recovery, Washing/Flushing, Physical Removal, Vegetation Cutting/Removal, Vacuum)

- ☐ In shallow nearshore areas with sensitive habitats, consider land-side access from roads, bulkheads, or other developed areas for operations.
- ☐ Avoid and minimize response disturbance to sensitive shoreline habitats and in particularly sand dunes and wetlands. Of particular concern are areas with Federally listed species in dune habitats such as tiger beetle, seabeach amaranth, and nesting birds. Contact the Environmental Unit to identify updated locations with these listed species in dune habitats.
- ☐ Where equipment or crews must access areas across tidal marsh, seagrass, or oyster habitats, use shallow draft vessels or specialized equipment with low pressure/flotation tires, equipment mats, walk boards, or other comparable methods to minimize disturbance, as applicable.
- ☐ Keeping clean wrack in general proximity is ideal, but it is not necessary to move it a substantial distance and back—use reasonable judgment.
- ☐ Following response work on beaches, return the beach to its original profile at the end of each day.
- ☐ Do not enter sites where birds are nesting or roosting and maintain a buffer of at least 300 ft from these sites. If birds are flushed, move away from the area, and observe a larger buffer distance to avoid and minimize disturbance.
- ☐ When working in or near bird migratory/wintering areas, work crews should be limited to the minimum number of personnel and equipment required to complete response activities in an efficient time frame and as is feasible to minimize disturbance.
- ☐ Be aware of the potential for sea turtle nesting activity if any operations are planned on Atlantic Ocean-facing sand beaches. Nests, eggs, and hatchlings may be present from May through November.
- ☐ Adult sea turtles, crawls, nests, eggs, hatchlings, and critical habitat should be protected during response activities on sea turtle nesting beaches, including hatchling turtles as they emerge from the nest and crawl to the sea. If a sea turtle nest is inadvertently excavated during assessment or response activities, all work shall cease in that area immediately and the Environmental Unit should be contacted.
- ☐ Upon locating any dead, injured, or sick sea turtle, birds, or marine mammals, or if eggs or nests are disturbed during response activity, initial notification must be made to the Environmental Unit as soon as possible. The Environmental Unit will make further notifications to the appropriate agency contacts.
- ☐ Contact the Unified/Incident Command (UC/IC) and Environmental Unit prior to conducting any response efforts that require substantial ground disturbance as additional SHPO coordination may be required. Federally recognized tribes with interest in the area and the THPO may be contacted if applicable.
- ☐ Cease all activities involving subsurface disturbance and immediately contact the UC/IC and Environmental Unit if prehistoric/historic artifacts, such as pottery or ceramics, projectile points, dugout canoes, metal implements, historic building materials, or any other physical remains that could be associated with Native American, early European, or American settlement are encountered at any time (and leave all artifacts in place). The SHPO and/or THPO must be notified. Response activities

shall not resume without verbal and/or written authorization from the UC/IC in consultation with the designated Historic Preservation Specialist (HPS) and document decisions; if there is no designated HPS then the UC/IC should receive guidance from the SHPO and/or THPO. If unmarked human remains are encountered during response activities, stop all work immediately and report to the UC/IC and Environmental Unit through your chain of command.

Staging Areas / Support Facilities

☐ Equipment and material staging areas must be located outside of areas of natural/native vegetation and known endangered species habitats, including federally threatened plant(s) that may be present in dunes. Areas proposed for equipment and material staging should be determined in consultation with the SHPO and/or THPO to avoid disturbance of archaeological sites or other historic properties. Contact the Environmental Unit (if established) for assistance.

☐ Use existing beach access areas and trails only.

☐ All trash resulting from the response should be removed from the area as appropriate or disposed of properly in covered wildlife-proof trash receptacles.

Waste Management

☐ All trash resulting from the response should be removed from the area as appropriate or disposed of properly in covered wildlife-proof trash receptacles.

Grounded or Displaced Vessel Response/Removal Operations

- ☐ Avoid and minimize response disturbance to sensitive benthic and shoreline habitats including tidal marshes, oyster reefs, seagrasses, sand beaches, and dunes.
- ☐ Contact the Environmental Unit prior to conducting any response efforts that require significant ground disturbance as U.S. Army Corps of Engineers (USACE) and/or State permits may be required. Additionally, substantial ground disturbance beyond the initial disturbance caused by the grounding may require additional SHPO coordination for historic sites and/or THPO for tribal coordination.
- ☐ Contact the Environmental Unit if significant sediment disturbance is anticipated, as further coordination with USACE may be required.
- ☐ Contact the Environmental Unit if filling of wetlands or surface waters or dredging that creates or expands surface waters is anticipated, as emergency permitting from State Agencies may be required.
- ☐ Turbidity control measures may be implemented if significant turbidity increases are expected during response actions. Such control measures include:
    - Install floating turbidity barriers with weighted skirts that extend to within 1-ft of the bottom around all work areas that are in, or adjacent to, surface waters, if heavy turbidity is expected.
    - Use these turbidity barriers throughout vessel removal to control erosion and siltation and ensure that turbidity levels within the project area do not exceed background conditions (i.e., the normal water quality levels from natural turbidity).
    - Position turbidity barriers in a way that does not block species entry to or exit from designated critical habitat.
    - Monitor and maintain turbidity barriers in place until the authorized work has been completed and the water quality in the project area has returned to background conditions.
- ☐ Avoid response vessel grounding, prop and bow/keel/skeg scarring, and prop washing in tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties.
- ☐ Avoid/minimize anchoring and spudding on tidal marsh, seagrass, and oyster reef habitats; anchor and spud on bare sand and mud bottoms, while avoiding archaeological sites or other historic properties. Consult with the SHPO and/or THPO to determine proximity of archeological/historic sites.
- ☐ If spudding on seagrasses cannot be avoided, fill spud holes to grade with clean sand, as feasible, to minimize impacts. Consult the Environmental Unit for any remediation requirements.
- ☐ Avoid/minimize shading of seagrasses with large vessels and barges for more than a few days; move large vessels and barges from over seagrasses onto bare sand or mud substrates when not undergoing active operations (such as in barge staging areas).
- ☐ Prior to hoisting, refloating, or repositioning grounded or displaced vessels, work crews should evaluate the immediate area and determine an ingress/egress path that will have the least impact to tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties. Contact the Environmental Unit for assistance.
- ☐ Temporary stakes/buoys should be used to mark the ingress/egress path, if applicable, to assist in staying on course and to avoid the areas of greatest tidal marsh, oyster reef, and seagrass habitat extent and quality.

- ☐ In shallow areas with sensitive shoreline and bottom habitats, consider land-side access from roads, bulkheads, or other developed or disturbed areas for response operations, where feasible.
- ☐ Where equipment or crews must access grounded or displaced vessels across tidal marsh, seagrass, or oyster habitats, use shallow draft vessels or specialized equipment with low pressure/flotation tires, equipment mats, walk boards, or other comparable methods to minimize disturbance, as applicable.
- ☐ Avoid pulling grounded or displaced vessels or other items across or onto tidal marsh, seagrass, and oyster reef habitats - items should be hoisted or refloated if possible. Use of lift bags, rollers, equipment mats, and other methods should be evaluated to minimize impacts, such as rutting and keel scarring.
- ☐ Avoid digging, jetting, excavation, and similar methods in tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties to refloat or reposition displaced vessels.
- ☐ If the above suite of habitat based BMPs cannot be applied, further USACE and State permits (see above) and Essential Fish Habitat (EFH) consultation may be required.

For further guidance and assistance with Best Management Practices (BMPs) during a response/incident, please contact the Environmental Unit (if established). BMPs that are utilized should be documented by the FOSC via the RRT3 ESA/EFH Biological Evaluation Guidance & Form for USCG Fifth District Coastal Zone.

ENVIRONMENTAL POINTS OF CONTACT

Primary Environmental Agencies / Organizations

If the Environmental Unit is not stood up, the key points of contact for environmental, wildlife, and historic preservation concerns during an oil spill response are provided below.

U.S. Coast Guard Fifth District Response Advisory Team (DRAT)

- David Pugh, david.e.pugh1@uscg.mil, 757-373-4133 (cell)
- Elisha Cook, elisha.fs.cook@uscg.mil, 757-630-1430 (cell)

National Oceanic and Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC)

- Frank Csulak, frank.csulak@noaa.gov, 732-371-1005

U.S. Fish and Wildlife Service (USFWS) Response Coordinators

- Sarah Shaeffer (NJ, NY, DE, Eastern PA/Delaware Watershed), sarah_scheaffer@fws.gov, 609-833-1476
- Jo Ann Banda (MD, Western PA, VA, WV, DC), joann_banda@fws.gov, 804-824-2413 (office), 804-694-7647 (cell)
- Brian Spears (NC), brian_spears@fws.gov, 251-284-5295 (cell), 251-928-9765 (office)

Department of the Interior (DOI)

- John Nelson, john_nelson@ios.doi.gov, 215-597-5012 (office), 215-266-5155 (cell)

Sector Delaware

Bay PREP Exercise

2023 Resources at Risk

1. Incident Name Delaware Bay PREP drill	2. Operational Period (Date/Time) From: 7 AUG 2023 To: 10 AUG 2023	RESOURCES AT RISK SUMMARY ICS-232-OS

3. Environmentally Sensitive Areas and Wildlife Issues

Site Name and/or Physical Location	Site Considerations
Cape Henlopen State Park	T/E shorebirds present and nesting; T/E insects and plants present along dunes.
Prime Hook NWR (DE)	T/E birds present and nesting, high bird concentrations
Pea Patch Island (Ft. Delaware State Park) (DE)	Thousands of colonial nesting birds
Higbee Beach WMA (NJ)	T/E shorebirds and gulls/terns present and nesting
Cape May Point State Natural Area (NJ)	T/E shorebirds present and nesting
Mouth of Cedar Creek (DE)	High numbers of shorebirds on flats

Narrative:

This report covers resources present in August in the waters and along the shoreline of Delaware Bay and the lower Delaware River from the mouth of the bay up to Delaware City (DE)/Finns Point (NJ). The drill scenario includes the release of 8,959 bbl of IFO 380, a heavy fuel oil (HFO), with the following characteristics:

- When spilled on water, HFO usually spreads into thick, dark-colored slicks, which can contain large amounts of oil. The most viscous oils will often break into discrete patches and tarballs, instead of forming slicks. Oil recovery by skimmers and vacuum pumps can be very effective early in the spill. Very little of this viscous oil is likely to disperse into the water column.
- HFO is a persistent oil; only 5-10% is expected to evaporate within the first hours of a spill. Consequently, the oil can be carried hundreds of miles in the form of scattered tarballs by winds and currents. The tarballs will vary in diameter from several feet to less than 1 inch, and they may be very difficult to detect visually or with remote sensing techniques.
- These oils can occasionally form an emulsion, but usually only slowly and after a period of days.
- Because of its high viscosity, beached HFO tends to remain on the surface rather than penetrate sediments. Light accumulations usually form a “bathtub ring” at the high-tide line; heavy accumulations can pool on the surface.

ESA-listed species are designated with FT (federally threatened) or FE (federally endangered) following the species name; state listed species are designated with SE or ST following the state abbreviation.

Shoreline:

Much of the bay shoreline is composed of mixed coarse-grained sand and gravel beaches. Bay inlets are lined with marshes; substantial marsh complexes occur along both the DE and NJ bay shorelines. Riprap shorelines/jetties are present in developed areas near Cape Henlopen and Cape May.

Birds:

Concentration areas are listed in the table above; however, marshes and tidal flats along the shoreline are all important habitats for birds. Delaware Bay is important habitat for shorebirds during their fall migration.

Bird Associated with Shorelines (beaches, marshes, and tidal flats):

Shorebirds, gulls, terns: Rufa red knot (FT, DE SE, NJ SE) and piping plover (FT, DE SE, NJ SE) are present along bay shorelines. Piping plover may be nesting at the following sites: Cape Henlopen State Park (DE), Prime Hook NWR (DE), Higbee Beach WMA (NJ), Cape May Point State Natural Area (NJ). Rufa red knots forage on beaches and flats. Other species of shorebirds, gulls, and terns may be present along DE and NJ shorelines including American oystercatcher (DE SE), black-necked stilt, spotted sandpiper, black skimmer (DE SE, NJ SE), common tern (DE SE), Forster’s tern (DE SE), Least tern (DE SE, NJ SE), and great black-backed gull.

Wading birds - Black-crowned night-heron (DE SE, NJ ST), yellow-crowned night-heron (DE SE, NJ ST), Cattle egrets (NJ ST) and other wading birds (herons, egrets) can be found along the shorelines of Delaware Bay. Yellow-crowned night-herons, cattle egrets, glossy ibis, and snowy egret may still be nesting in August.

Raptors - Bald eagles (NJ SE), osprey (NJ ST), and peregrine falcons (NJ/PA SE) can be present along the shoreline and forage in bay waters. Osprey are nesting in August, and nests are relatively common along the Delaware shoreline of the bay. Other species of raptors (hawks) may also be present).

Other - Resident marsh birds present and nesting include clapper rail and marsh wren. Other passerines may be present in marsh and upland areas, including black rail (DE SE), sedge wren (DE SE), and saltmarsh sparrows.

Bird Associated with Bay waters: Species present and feeding or rafting in bay waters include resident waterfowl (American black duck, Canada goose, hooded merganser, mallard), double-crested cormorants, gulls, and terns. Pelagic seabirds may also be present towards the mouth of the bay, including Wilson's storm-petrel and shearwaters.

Direct oiling of birds reduces the buoyancy, water repellency, and insulation provided by feathers, and may result in death by drowning or hypothermia. Preening of oiled feathers may also result in ingestion of oil resulting in irritation, sickness, or death. Adult birds bringing even small amounts of oil back to their nests on their feet or feathers may reduce the hatching success of eggs or survival of young.

Fish/Marine Invertebrates:
Shortnose sturgeon (FE) and Atlantic sturgeon (FT) are present in Delaware Bay waters. Giant manta ray (FT) may also be present in bay and coastal waters. Delaware Bay is a major nursery area for sandbar sharks and a core use area for sand tiger sharks – it is a designated HAPC for both species. EFH is present for many highly migratory and resident (shelf) fish and invertebrate species, and the area supports productive fisheries for these species. Invertebrate species present in the bay include horseshoe crabs, blue crab, blue mussel, whelks, quahogs, softshell clams, American lobster, and longfin squid. Oyster reefs are present in the upper portions of Delaware Bay and several tributaries to the main bay (e.g., Milford Neck).

Larval and juvenile life-stages are especially sensitive to spilled oil because they inhabit shallow, protected waters, are less mobile, and are more sensitive to oil toxicity.

Sea turtles: Loggerhead sea turtles (FT) are common in bay waters, and green (FT) and Kemp's ridley (FE) sea turtles can also be present. Direct effects of oil exposure on sea turtles may include oiling of sensory organs, reddening and sloughing off of the skin, dysfunction of the salt gland, uptake of oil in the gastrointestinal system, and disturbed diving and respiration patterns.

Marine Mammals:
Bottlenose dolphins are abundant in nearshore and offshore waters. Oil may cause irritation of skin and mucous membrane surfaces in marine mammals. Inhaling vapors may cause irritation of the lungs. These impacts are more commonly reported for spills in protected bays where oil exposure tends to be prolonged.

Insects: Little white tiger beetle (DE SE) and beach-dune tiger beetles can be found at Cape Henlopen State Park. Beach-dune tiger beetle can also be found at other sites along the Delaware shoreline (Slaughter Beach, Beach Plum Island, Big Stone Beach, Logan Creek Wildlife Area). Care should be taken not to disturb these habitats during response activities. Contact state natural resource agencies for exact locations prior to beginning cleanup operations.

Other shoreline resources: Seabeach amaranth (FT) is present at Cape Henlopen State Park. Other rare and endangered plants are present along the Delaware and New Jersey shorelines of the bay. Care should be taken not to disturb plants during response activities. Contact state natural resource agencies for exact locations prior to beginning cleanup operations.

4. Archaeo-cultural and Socio-economic Issues

Narrative:
Archaeological and historical sites are present along the bay shorelines. Some historic sites are present in bay waters.

Managed areas:
USFWS properties: Prime Hook NWR and Bombay Hook NWR (DE); Cape May NWR (NJ) are present along the shoreline of the bay.
*Delaware***:** Cape Henlopen and Great Marsh Preserve state parks are present along the shoreline. Multiple wildlife areas are present along the shorelines (managed by DNREC Division of Fish and Wildlife).
New Jersey: Many state WMAs (managed by NJ Division of Fish and Wildlife) and Preserves (NJ Department of Natural Lands Trust) are present along the New Jersey Shoreline.
The Nature Conservancy (TNC) owns two properties bordering Delaware bay: Eldora nature preserve, Seabreeze Preserve.

Recreational and commercial fishing are common in the bay. NJ Aquaculture leases are present in the upper portions of Delaware Bay.

Ferry routes potentially impacted include the Cape May/Lewes Ferry and Fort Mott/Fort Delaware Ferry.

Threatened & Endangered Species
Within Sector Delaware Bay

Species and Habitats at Risk during Oil Spills

Species

Many wildlife species in Sector Delaware Bay's AOR are at particular risk of harm from oil spills, especially considering the area's position in a major bird migration flyway. This section focuses on species at risk according to input from local wildlife trustees and their status on the federal and/or state Threatened & Endangered (T&E) lists.

Key species are listed in the following table. For a full list of species at risk, including their listing status, breeding season, and critical habitat within Sector Delaware Bay, click the following link (this list is subject to change):

https://acrobat.adobe.com/id/urn:aaid:sc:VA6C2:a2e31634-60c2-4e7c-98f2-5475cda9d564

Table 3. Key species at risk in the Sector Delaware Bay AOR.

Species	Status
Mammals & Marine Mammals	
Indiana Bat (*Myotis sodalis*)	Endangered NJ, PA
Little Brown Bat (*Myotis Lucifugus*)	Endangered
Northern Long-eared Bat (*Myotis septentrionalis*)	Endangered
Harbor Seal (*Phoca vitulina*)	Marine Mammal Protection Act
Gray Seal (*Halichoerus grypus*)	Marine Mammal Protection Act
Birds	
Black Rail (*Laterallus jamaicensis*)	Endangered in NJ
Piping Plover (*Charadrius melodus*)	Threatened
Roseate Tern (*Sterna dougallii dougallii*)	Endangered (Northeast population)
Red Knot (*Calidris canutus rufa*)	Threatened & Endangered DE, NJ, PA
Reptiles	
Bog Turtle (*Glyptemys muhlenbergii*)	Threatened
Eastern Massasauga (*Sistrurus catenatus*)	Threatened
Green Sea Turtle (*Chelonia mydas*)	Endangered
Hawksbill Sea Turtle (*Eretmochelys Imbricata*)	Endangered
Kemp's Ridley Sea Turtle (*Lepidochelys kempii*)	Endangered
Leatherback Sea Turtle (*Dermochelys coriacea*)	Endangered
Loggerhead Sea Turtle (*Caretta caretta*)	Endangered
Diadromous Fish	
Atlantic Sturgeon (*Acipenser oxyrinchus oxyrinchus*)	Species of concern
Shortnose Sturgeon (*Acipenser brevirostrum*)	Endangered
Crustacean	
Horseshoe Crab (*Limulus polyphemus*)	Not listed
Insect	
Bethany Firefly (*Photuris bethaniensis*)	Endangered DE

Further information on species at risk in the Sector Delaware Bay area can be found here:

Habitats

A habitat is considered at risk of harm from oil spills if it is particularly sensitive to damage, hosts a wide variety of organisms, or acts as key habitat for a T&E species. The following locations are considered at risk and should be treated with special consideration to prevent damage during oil spills.

Acknowledgements

The Steering Committee for the Oil Spill Recovery Institute (OSRI) Migratory Bird Standards and Protocols Project wishes to acknowledge and thank the following workshop participants who helped to develop *Best Practices for Migratory Bird Care During Oil Spill Response:*

Catherine Berg — U. S. Fish & Wildlife Service — Anchorage, AK
Pamela Bergmann — U.S. Department of the Interior — Anchorage, AK
Barbara Callahan — International Bird Rescue & Research Center — Anchorage, AK
Matt Carr — U.S. Environmental Protection Agency — Anchorage, AK
Curt Clumpner — International Bird Rescue Research Center — Lynnwood, WA
Amy Cocanour — U. S. Coast Guard — Washington, D.C.
Craig Giggleman — U.S. Fish and Wildlife Service — Arlington, TX
Eileen Gilbert — Tri-State Bird Rescue & Research, Inc. — Newark, DE
John Kenney — Maine Department of Inland Fisheries & Wildlife — Bangor, ME
Chris Lane — Washington Dept. of Fish & Wildlife — Olympia, WA
Ginny Pierce — N/A — Port Deposit, MD
Corey Rossi — U. S. Department of Agriculture — Palmer, AK
Sharon Schmalz — Wildlife Rehabilitation & Education, Inc. — League City, TX
Claudia Slater — Alaska Department Fish & Game — Anchorage. AK
Heidi Stout — Tri-State Bird Rescue & Research, Inc. — Newark, DE
Jan Thorman — U.S. Department of the Interior — Washington, D. C.
Dave Trudgen — BP Exploration — Anchorage, AK
Jan White — Wildlife Publications — Maple Valley, WA
Michael Ziccardi — University of California — Davis, CA

Members of the Steering Committee:

Catherine Berg — U. S. Fish & Wildlife Service — Anchorage, AK
Pamela Bergmann — U.S. Department of the Interior — Anchorage, AK
Barbara Callahan — International Bird Rescue & Research Center — Anchorage, AK
Claudia Slater — Alaska Department of Fish & Game — Anchorage. AK
Kelley Weaverling — Prince William Sound Audubon Society — Cordova, AK

This document is based on the work of many individuals and organizations in the field of bird deterrents, rescue, and rehabilitation. The Steering Committee gratefully acknowledges the generous assistance of those who permitted their publications to be excerpted or otherwise used here.

Thanks to the Prince William Sound Oil Spill Recovery Institute for providing the funding that made the February, 2001 workshop possible.

Introduction

Background

Best Practices for Migratory Bird Care During Oil Spill Response (*Best Practices)* is the result of a Fish and Wildlife Countermeasures Coordination Project undertaken by the U.S. Fish and Wildlife Service (USFWS). The goals of the project include the development of national "best practices" using established protocols for keeping unoiled birds away from an oil spill and for dealing with oiled birds. Establishing a standardized approach helps protect wildlife resources, enables On-Scene Coordinators (OSCs) to focus on other aspects of spill response, and helps instill public confidence in overall response activities.

A group comprised of natural resource management agencies, rehabilitators, veterinarians, and industry representatives developed this document at a 3-day workshop held in February 2001 in Anchorage, Alaska. This workshop was a follow-up to the March 2000, Wildlife Countermeasures Session on the Effects of Oil on Wildlife Conference held in Myrtle Beach, South Carolina. Prior to the Alaska workshop, information was distributed through a variety of forums to interested parties. The outreach included a solicitation for copies of existing relevant standards and protocols. As a result of this effort, 26 documents were collected. Of those, 11, which were the most current and relevant, were selected by the workshop Steering Committee to serve as primary source documents for the workshop. (See *References*, page 45.)

A draft of the "Best Practices" document was presented at the March 2001 International Oil Spill Conference in Tampa, Florida, at a special session entitled *Migratory Bird Countermeasures Coordination Project*. This was an open meeting and comments were solicited and discussed. The U.S. Fish and Wildlife Service accepted written comments on the draft document through July 31, 2001. During this time, the document also underwent internal USFWS review.

Intended Uses

This document, *Best Practices for Migratory Bird Care During Oil Spill Response*, is intended for use by the U.S. Fish and Wildlife Service and other natural resource management agencies, oiled bird rehabilitators, OSCs, and Potentially Responsible Parties (PRPs) as a guide in:

- Developing appropriate sections of Area Contingency Plans;

- Evaluating contractors for bird capture and rehabilitation;
- Making informed choices during spill responses; and
- Evaluating oiled bird rehabilitation activities to improve field practices.

The creators of this document set out to define and recommend the best practices for their field with the aim of promoting the welfare of migratory birds during an oil spill response. Actual bird responses will depend on factors including the size of the spill, species involved, type of product spilled, time of year, and location. It is generally recognized that there are significant differences between a spill affecting 10 birds and one involving 1,000 birds. It is important that spill responders and pre-spill planners recognize that the degree of effort and complexity in bird response can be significant when comparing small and large events. This document is intended to help pre-spill planners and spill responders make informed decisions keeping the best interests of the birds in mind.

In defining the best practices of a migratory bird response, each aspect of a response is discussed separately. Topics include safety, training, capture and handling, stabilization and rehabilitation, and release criteria. Much of what is discussed in this document describes factors that constitute highest and best migratory bird care and recommendations for achieving the highest standard of care.

This document is not intended for use as a training manual. It is to serve as guidance for acquiring the best achievable care for birds during an oil spill response. Neither is this document an exhaustive list of techniques in this field, in which practical knowledge is being continuously refined and developed. It is intended that this document will be periodically reviewed and updated. If techniques not included here are proposed during an oil spill response, the U.S. Fish and Wildlife Service will seek the most current and best information on which to base an educated decision on the appropriate course of action.

Criteria for Evaluating Rehabilitation Groups

The following criteria will be used when considering and evaluating bird rehabilitators for conducting oiled-bird response.

- Hold all necessary permits for bird-related response activities;
- Experience in the capture, treatment, and care of oiled birds;
- Experience conducting bird-related response activities within the Incident Command System structure;

- Sufficiently trained, equipped, and experienced staff, and ability to train and equip personnel and volunteers for bird-related response during an emergency response;
- Ability to quickly mobilize to perform bird capture, field evaluation, stabilization and transport, including remote locations if necessary;
- Access to appropriate facilities adequate for treating and housing oiled birds:
    - Ability to establish and operate bird intake, holding, and isolation areas within 12-24 hours of wildlife response activation; and
    - Ability to establish and operate bird cleaning and pre-release areas within 48 hours of wildlife response activation.
- Agreement with a licensed veterinarian, experienced in the treatment of oiled birds, to provide any necessary veterinary medical care; and
- Use of best practices as outlined in the remainder of this document.

Chapter

1

Responsibility & Organization

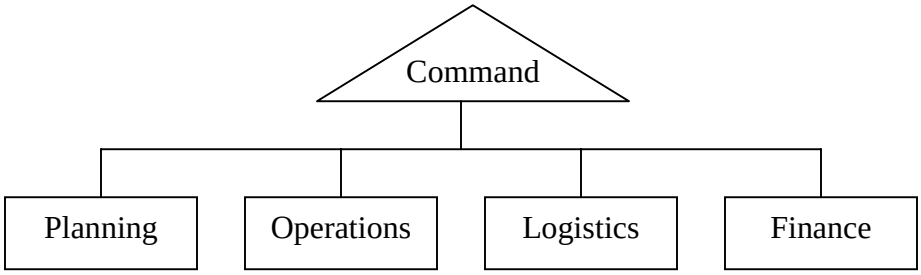
Trust Responsibilities

In the event of an oil spill, trust responsibilities for migratory birds and their habitats are clearly given to the U.S. Fish and Wildlife Service through several federal legislative statutes including the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), Clean Water Act (CWA), National Oil and Hazardous Substances Pollution Contingency Plan (NCP), the Migratory Bird Treaty Act (MBTA), and the Endangered Species Act (ESA). States also have trust responsibilities for migratory birds within their state boundaries under various state statutes. Because of these shared trust responsibilities, both federal and state agencies are required to respond to spills, or potential spills, that may impact migratory birds. To facilitate efficient and effective coordination during a migratory bird response, federal and state agencies may consider developing Memorandums of Agreement (MOA's) or Memorandums of Understanding (MOU's) that pre-designate regional primary points of contact, establish lead representatives, and define roles for natural resource emergency situations.

Organizational Structure of a Wildlife Response

The organizational structure of a migratory bird response should fit within the Incident Command System (ICS) or the overall spill response structure. Federal directives and some states mandate use of the ICS by their agencies as the emergency management system for oil and hazardous substance spill response. The ICS is a standardized on-scene emergency management system designed to adopt an integrated organizational structure equal to the complexity and demands of an incident without being hindered by jurisdictional boundaries. A simplified chart of the ICS response organizational structure follows:

Example: Response Organization



Command

The Command or Unified Command, which includes the State On-Scene Coordinator and Federal On-Scene Coordinator, is responsible for authorizing and coordinating all incident operations. While the Command may include other entities such as a Responsible Party On-Scene Coordinator, only Federal and State On-Scene Coordinators have authority over bird-related response decisions. The OSC will consult with the USFWS and state agencies when migratory birds may be impacted to determine appropriate response measures. For incidents that could significantly impact trust resources such as endangered species, the OSC may request that an agency representative become part of the Command.

Planning

When trust resources, such as migratory birds, may be affected by an oil spill, USFWS and state wildlife agency representatives will likely become involved in the response effort through the Planning Section. The representatives provide input on the protection of sensitive resources and how to minimize impacts to trust resources like migratory birds. Most bird-response planning occurs within the "Environmental Unit" of the Planning Section. The Planning Section identifies all bird-related response activities and describes those activities in the Incident Action Plan. Depending on the nature and extent of the spill, such activities may include wildlife reconnaissance, carcass recovery, hazing, wild-bird capture and transport, safety and communications, and rehabilitation and release. The Incident Command must approve all migratory bird response actions. The responsibilities of the Planning Section related to bird response include:

- Identifying sensitive areas, locating birds-at-risk, and recommending response priorities;
- Identifying the need for, and obtaining permits, consultations, and authorizations required by the provisions of the Endangered Species Act, MBTA, and other wildlife laws; and

- Developing a plan for bird protection and response strategies (e.g., removing oiled carcasses, pre-emptive capture, hazing, and capture and treatment).

Operations

A USFWS representative or state wildlife agency representative should also serve within the Operations Section, to provide oversight of the bird-related and other wildlife response activities. Bird-related response and other wildlife activities, including the operation of a wildlife rehabilitation center, are managed under the "Wildlife Branch" of the Operations Section. It is critical that all wildlife response activities be coordinated and communicated through the Planning Section, Situation Unit, which is responsible for maintaining the communication of critical incident information vital to establishing and maintaining an effective command and control environment. The responsibilities of the Operations Section related to bird response include:

- Minimizing migratory bird losses during spill response;
- Overseeing and coordinating all activities of private migratory bird care groups, including groups employed by the responsible party;
- Coordinating early aerial and ground reconnaissance of birds at the spill site, and reporting the results to the Situation Unit Leader;
- Collecting oiled carcasses,
- Employing bird hazing measures as authorized in the Incident Action Plan;
- Recovering and rehabilitating impacted birds;
- Collecting necessary samples; and
- Identifying and maintaining a central bird processing center for evidence tagging, transportation, veterinary services, treatment and rehabilitation, storage, and other support needs.

Logistics

The Logistics Section is responsible for providing facilities, services, and material in support of the incident response. Bird-related support needs are identified in the Incident Action Plan and acquired within Logistics.

Finance

The Finance Section is responsible for financial and cost analysis aspects of the spill response incident.

Chapter

2

Safety and Human Health

Worker health and safety are of primary importance in any bird rescue and rehabilitation effort. The earliest phases of a bird-related response during an oil spill are generally the most hazardous to human health and safety. Thus, safe practices during field collection of birds must be a priority. Bird rescue programs will not be initiated unless personnel can conduct activities safely.

As with all spill response activities, the bird rescue and rehabilitation effort needs to be coordinated and monitored by the spill response command center operations, safety, and medical staffs. A written site safety plan, in accordance with 29 CFR 1910.120(b)(4), must be developed for the rehabilitation facility and submitted to the Spill Safety Officer. If field activities are on-going for bird response, the site safety plan needs to be expanded to include these activities and any specialized equipment that will be used (e.g., net guns, cannon nets, propane cannons).

Summary of Safety Precautions

Bird rescue and rehabilitation workers can minimize the risks associated with physical and chemical hazards by following the precautions below:

- Observe all industrial hygiene safety precautions stated in the Health and Safety Plan.
- Know how to use the Material Safety Data Sheet (MSDS).
- Take all required training regarding the hazards of the work task, and in the proper use and limitations of personal protective equipment.
- Wear personal protective equipment approved for, and appropriate to, the oil spilled to minimize contact with contaminated materials and inhalation of vapors.
- Maintain an awareness of field conditions and hazards (terrain, climate, flora/fauna, etc.) to prevent slips, trips and falls.

- Keep all oil, cleaning compounds, and contaminated materials away from skin, face, and eyes.
- Always remove protective equipment and wash hands and face with soap and water or approved cleaners before eating, drinking, or smoking.
- Ensure that all oiled personal protective equipment, supplies, and waste material are placed in appropriate receptacles.
- Ensure that work areas are kept clean.
- Never conduct bird rescue work alone; always work in teams.
- Keep birds at or below one's waist level to protect the face and eyes from pokes, bites, and scratches.
- Report all injuries and illnesses to the supervisor and/or Command Center medical staff.
- Be alert for over-heating and hypothermia.
- Don't overwork. Eat regularly and well.
- Never eat, drink, or smoke in bird handling areas.
- If you have immunosuppressive conditions, or you are pregnant, do not have direct contact with birds and consult your physician prior to participating in other aspects of bird-related response activities.
- Update tetanus shots.

Training for Bird Rescue/Rehabilitation Personnel

In addition to mastering specific bird rescue and rehabilitation tasks, personnel must be trained to recognize and minimize risk of injuries from oil-related and physical hazards associated with bird response operations prior to being allowed to participate in on-site activities. Elements of required and recommended training will vary depending on the tasks of the individuals involved in the response. Training-hour requirements and specific courses vary with level of involvement, agency policy, and OSHA and state regulations.

Required Training

29 CFR 1910.120(e) establishes the training required for hazardous operations site workers, including supervisors. All oiled-bird rescue and rehabilitation personnel must be trained to the minimal levels required in 29 CFR 1910.120 (e)(3)(iii). In addition, there

must be adequate on-site supervision by persons who meet the training requirements of 29 CFR 1910.120(e)(4).

Recommended Training

In addition to the training required by federal regulations, further training is highly recommended (and mandated for USFWS spill response personnel) for safe and efficient operations during a spill response. This guidance is considered a minimum essential training for bird rehabilitators in accordance with the goal of establishing best practices.

As a minimum, any personnel conducting bird deterrence or bird hazing activities should attend an 8-hour bird-deterrent training workshop and, if using pyrotechnics or firearms, should also attend 8-hour firearm safety training and 4-hour range training. Bird-capture personnel, field stabilization personnel, and bird transport personnel should attend a 16-hour basic rehabilitation skills training. Bird washing personnel should attend a 4-hour bird washing skills training session.

Personnel operating a boat should be licensed or certified with 24-hour watercraft operator safety training. Anyone riding in a boat should only ride with a certified or licensed operator. Response personnel performing field functions (e.g. bird surveys) while riding in a small aircraft should complete 8-hour basic aviation safety training. As indicated above, any personnel handling firearms should attend 8-hour firearm safety training and 4-hour range training. All teams operating in the field should have at least one person in the party certified in First Aid and CPR. Response personnel participating in the Incident Command Center should be trained to a minimum level of ICS300.

Table 1 summarizes basic training requirements and recommendations as discussed in detail above for each operational group.

Table 1. Summary of training essential to implementing "best practices" when responding to oiled migratory birds.

Training / Personnel	HAZWOPER	ICS 100-300	Aircraft Safety	Boating Safety	Firearm Safety	First Aid/ CPR	Basic Rehabilitation Skills	Bird washing	Supervisory and Crisis Management
USFWS Response[1]	R	R	R	R	R	R	-	-	-
Rehab Management[2]	R	R	-	-	-	H	H	H	H
Initial Assessment[3]	R	-	H	H	-	H	-	-	-
Bird Deterrent	R	-	-	H	H	H	-	-	-
Field Workers[4]	R	-	-	H	-	H	H	-	-
Facility Workers[5]	R	-	-	-	-	-	H	H	-

R = Required training, if performing the activity
H = Highly recommended for establishing best practices, if performing the activity
[1] = Training requirements established by Director's memorandum March 9,1998
[2] = Supervisory personnel and personnel in-charge.
[3] = Personnel conducting resources-at-risk reconnaissance surveys
[4] = Bird capture teams, field stabilization units, transport personnel, etc.
[5] = Bird washers, cage cleaners, pen monitors, etc.

Personal Protective Equipment

Personal protective equipment (PPE) must be used in accordance with 29 CFR 1910.120 (g)(3) to protect wildlife response personnel from exposure to hazardous substances. To guard against injury from birds, all workers should wear approved personal protective equipment appropriate to their task.

Recommended PPE

- Full eye protection, i.e., goggles, safety glasses, or face shield (Birds will peck when under stress and should be considered dangerous as they will aim for eyes.);
- Oil resistant rain gear or oil protective clothing (coated Tyvek, Saranex, etc.);
- Gloves (neoprene or nitrile rubber) that are oil resistant, waterproof, and provide protection against pecking and sharp talons;
- Non-skid shoes/boots, which are oil resistant and waterproof;
- Ear protection (muff or ear plug type) when using pyrotechnic devices or operating machinery; and
- Personal flotation device when working on or near water.

Respiratory protection from organic vapor hazards may also be required for some operations. If respirators are used, respiration training and fit testing are required in accordance with 29 CFR 1910.134. (USFWS personnel are not allowed to operate in an environment requiring protective gear above Level D as established in 29 CFR 1910.120, Appendix B, Part A.). All workers must be trained, in accordance with 29 CFR 1910.132(f), on the proper use and limitations of all personal protective equipment prior to using the equipment.

In addition to hazards from oil, numerous physical hazards may be associated with bird rescue activities. To protect against bites and scratches, appropriate clothing and equipment should be worn underneath the oil protective equipment whenever necessary. Workers should be aware of temperature, weather, and other environmental conditions and use personal protective equipment to guard against dangerous waters, frostbite, hypothermia, heat-stress disorders, and infectious diseases.

There is a potential health risk to poultry, farm and domestic animals (including pets) from clothing or equipment that has been in contact with wild birds. Decontamination procedures must be established and workers are required to return used oil spill response equipment and supplies to their supervisor in accordance with 29 CFR 1910.120(k).

Personal Safety When Handling Birds

Human safety is the primary consideration in bird handling; the safety of the bird being handled is important but secondary. In accordance with 50 CFR 21.31, bird capture and handling may only be done by trained and permitted individuals. Handling and restraint techniques appropriate for specific species need to be applied. M.E. Fowler's book, *Handling and Restraint of Wild and Domestic Animals* (Fowler, 1995) serves as a preliminary guide to handling procedures.

Capturing oiled birds is often physically and emotionally stressful for bird-handlers. Dehydration, exhaustion, and poor nutrition can all affect a person's ability to assess and react to a dangerous situation. It is therefore important that workers stay well hydrated and eat nutritionally sound meals. Rest is equally important. A tired, stressed person, the presence of oil, and hazardous terrain are a dangerous combination. Workers should be aware of their own condition and also the conditions of those around them. The safety of all depends on the alertness of each individual.

All rescue/rehabilitation work crews should have a first aid kit on site for minor cuts and scrapes. If bitten, scratched or otherwise injured, report the injury to a supervisor and seek treatment. Each crew or team, should be assigned at least one person trained to provide emergency first aid, including CPR.

Other safety issues are covered in Chapter 4, *Capture, Handling, and Transport*, page 18.

Zoonoses

Wild birds may carry diseases that are transmissible to people. Diseases that are transmitted from animals to humans are called *zoonoses*. They may be viral, bacterial, fungal or parasitic in nature. They can be transmitted to humans by four primary routes:

- Inhalation of particles (spores, bacteria) in the air;
- Ingestion of feces (i.e., projectile feces, poor hygiene);
- Dermal contact; and
- Indirectly, via a vector (e.g. needle sticks, insect bites).

NOTE: Individuals who have immunosuppressive conditions are more susceptible to contracting zoonotic diseases.

To reduce risk of contracting zoonotic diseases, and in accordance with best practices, bird handlers should always:

- Wash hands thoroughly with soap and water after handling birds.

- Wash hands well before and after eating.
- Avoid smoking or eating near birds; do so in designated areas only.
- Clean and treat all cuts and scratches.
- Use appropriate PPE.
- For a list of zoonotic diseases, modes of transmission, and symptoms, see Appendix 2.

Hazardous Substances

Bird rescue and rehabilitation workers may be exposed to spilled oil, and must be so informed in accordance with 29 CFR 1910.1200(e). Prior to handling a contaminated bird, the Material Safety Data Sheet (MSDS), as established in 29 CRF 1910.1200(g), for the spilled material should be reviewed and all recommended precautions followed. In accordance with 29 CFR 1910.120(h), workers and the rehabilitation facility shall be periodically monitored, using calibrated instruments and devices to determine airborne concentrations of petroleum products (e.g., benzene). Appropriate PPE is required (see *Personal Protective Equipment*, page 11). Ventilation in all work areas should prevent the buildup of airborne contaminants. (See *Facilities*, page 36*)*

A portion of the rehabilitation facility should be designated for the storage of contaminated clothing, equipment and medical waste until the items can be decontaminated or disposed in accordance with 29 CFR 1910.120(k)(2-5).

Volunteers

Wildlife response programs regularly use volunteers, particularly at the rehabilitation facility. Wildlife response managers need to ensure that volunteers are appropriately trained, supervised, and informed of all hazards in accordance with 29 CFR1910.120(i). A comprehensive volunteer management program is an essential component of an efficient wildlife response. This management program needs to address, at a minimum, volunteer safety, training, supervision, scheduling, and liability.

Chapter

3

Deterrence

Following an oil spill, it may be necessary to initiate a deterrence program that disperses and excludes unoiled birds from contaminated areas to reduce bird mortality. If warranted, deterrence activities are initiated as soon as possible following an oil spill to prevent birds from establishing or continuing regular use patterns within a contaminated area. Any delays may decrease the effectiveness of the program in reducing the overall numbers of oiled birds. Deterrent devices used to disperse birds include both visual and auditory techniques, using both simple and sophisticated devices in order to respond to the unique habits of different bird species, surrounding environments, and the spill situations. Information necessary to help determine whether or not to begin a deterrence program includes, but is not limited to: spill location, species present, species type, time of year, availability of nearby uncontaminated habitat, and location of species in relation to the spill.

All deterrence activities require authorization from appropriate natural resource management agencies and oversight by the designated USFWS representative. Only those persons trained and certified in bird deterrence techniques will be allowed to conduct these activities. Deterrence activities must be authorized and coordinated within the Incident Command System. A communication line will need to be established between deterrence personnel and Air Operations to avoid potential bird/aircraft collisions.

Aerial and Ground Surveys

Reconnaissance surveys for resources-at-risk are conducted as soon as practical following the spill. The main objective of these surveys is to evaluate the number, species and locations of birds that could be impacted by the oil spill. All surveys will be authorized and coordinated through the ICS. The scope and frequency of subsequent surveys will be incident-specific. Written reconnaissance survey results and maps are submitted to the appropriate ICS subunit within the Planning Section. The location and number of birds will need to be plotted on maps or charts for use by the Situation Unit.

Experienced personnel are essential for effective surveillance. An observer should have the appropriate knowledge to properly identify species, record behavioral

characteristics, be familiar with local area ecology, and make other pertinent observations. Ideally, an aerial survey should be done by helicopter, but fixed wing aircraft can also be used.

Deterrence Program Considerations

Consider the following points before beginning any deterrence operations:

> **NOTE:** No attempt should be made to disperse oiled birds.

- Worker safety.
- Local habitats and species.
    - Some species, especially those found associated with a human environment are difficult to deter, especially if chosen deterrents mimic sounds or visual elements associated with that environment.
    - Consider the potential effects of human activity and disturbance on sensitive habitats and species.
    - Molting birds are not easily dispersed, and require a combination of different techniques.
- Availability of "clean" habitat within a reasonable distance.
    - Avoid dispersing birds into areas that might become contaminated; be aware of oil trajectory predictions.
    - Determine if "clean" habitat can be made more attractive (e.g., temporarily limiting access to people, boats or certain activities)
- Appropriate technique.
    - Deterrence will be most effective if the entire area of concern can be hazed as continuously as possible. As a general rule, do not start a deterrence operation that cannot be maintained for the required duration.
    - Automatically operated devices, which require checking only once a day or less, may be used when staffing is limited, during bad weather, or at night.
    - In general, expose the area to a variety of devices and techniques, with random variations to control habituation. Be prepared to back off as events dictate.

- Appropriate technique cont.
    - In general, most deterrence activities would probably not be effective for areas larger than seven to 10 miles in length or diameter.
    - Highly mobile devices (e.g. sound-emitting buoys) that can influence large radiuses are necessary for larger spills on water.
    - Some types of oil, like fuel, are highly flammable during the first hours following a spill, due to the presence of high concentrations of volatile oil fractions. Techniques with potential to induce sparks are to be avoided in these situations.
- Potential side effects.
    - The effects of sound-emitting devices on humans will influence whether or not some techniques will be acceptable to local residents.

Once the decision to deter or haze unoiled birds has been made, remember that each spill situation will be unique and preplanned deterrence activities must be viewed as tentative at best. The pros and cons of every deterrence operation are to be evaluated in view of site- and incident-specific details and after consultation with local experts. If pyrotechnics are used, permits may also be required from the local fire marshal.

See *Appendix 3,* for a discussion of the advantages and disadvantages of various deterrence methods.

Pre-emptive Capture

Pre-emptive capture includes the capture, handling, transportation, short-term holding and release of healthy, uncontaminated birds. According to 50 CFR 21.31(f)(1)(i), permitted rehabilitators are authorized to temporarily possess healthy, unaffected birds for the purpose of removing them from imminent danger. Pre-emptive capture of federally listed threatened or endangered species should not be conducted without prior consultation with, and approval by, the USFWS under Section 7 of the Endangered Species Act. No capture activities may be conducted in pinniped or seabird rookeries. Preemptive capture must be supervised by the USFWS and authorized by the Incident Commander

This secondary response option has limited application based on species-specific criteria. The primary concerns when conducting pre-emptive capture are human and

bird safety and minimizing transportation and holding times. Safety of the birds should be focused on stress reduction. Minimize stress by:

- Having the equipment necessary to handle and transport birds as quickly and efficiently as possible;
- Minimizing the number of vessels, aircraft, all-terrain vehicles, etc. to herd and capture birds in a given area;
- Avoiding unnecessary noise and disturbance during the capture effort;
- Never pursue the birds to the point of exhaustion; and
- Minimizing human contact with the birds except to provide veterinary care.

Pre-emptive capture techniques for birds may be the same as those used by bird banding operations such as mist nets and herding molting or flightless birds into corrals. All techniques should be considered in consultation with the U.S. Fish and Wildlife Service.

Chapter

4

Capture, Handling, & Transport

Capture

Human safety is a primary consideration before any retrieval effort is made. Hazardous weather conditions, unsafe footing, icy rivers, or dangerous seas may preclude a bird rescue attempt. In addition, captive birds are often aggressive and should be regarded as dangerous in any sort of confining situation. Only authorized and trained individuals are allowed to undertake the capture and treatment of oiled birds under the direction of a permitted rehabilitator. Teamwork is essential to minimize additional stress to the birds. To capture and handle oiled birds, rehabilitators must have appropriate licenses and permits in accordance with 50 CFR 21.31. Land-owner or manager permission may be necessary to access capture sites. All capture activities are developed within the Planning Section, coordinated within the ICS, and must be authorized by the Incident Command.

A bird capture program should be implemented as early as is safely possible in a spill response effort to increase the survival rate of birds. Captured birds are to receive medical evaluation and preliminary treatment as quickly as possible. The conditions under which oiled birds are captured can vary widely from one spill to another. A variety of capture methods and techniques are employed to maximize capture success. The effectiveness of rescue efforts will be influenced by factors such as time of year, type and amount of material spilled, species involved, local terrain, tides, and weather. Birds can be safely collected and transported in a variety of challenging conditions when rescue workers adhere to basic rules.

Capture Rules

- Ensure personnel are trained;
- Put safety first;
- Wear protective clothing.
- Work in teams; never work alone;

- Report any injuries;
- Do not allow the presence of domestic animals; and
- Do not pursue animals until they are exhausted.
- As a preliminary reference for developing a capture strategy, consult the summary of bird characteristics, natural history, and specific species concerns located in *Appendix 4*.

Capture Planning

In addition to trained personnel, well developed plans will ensure a safe and successful capture program.

Reconnaissance Plan

This plan describes the steps rescuers will take to survey birds in oiled offshore waters, near-shore waters, and along shorelines, as well as birds in areas that could be oiled. The reconnaissance plan also calls for surveys of nearby feeding, loafing and roosting areas to detect oiled birds that may have moved away from contaminated sites. Knowledge of the local area ecology is critical.

Capture Plan

Capture plans are site specific and address the following:

- Safety of personnel and birds from chemical and physical hazards;
- Personal protective equipment and clothing;
- Capture equipment and methods;
- Site access and egress;
- Bird approach and disturbance of unoiled birds;
- Adequate search coverage;
- On-site holding;
- Special site considerations (e.g. sensitive habitat, rookeries, cultural resources/historic properties); and
- Species prioritization for capture, as provided by USFWS.

Safety Plan

A safety briefing or plan must be approved by the ICS Safety Officer and available to all members of the capture team. The safety plan includes required personal protective equipment, communication instructions, and separate contingency plans for on-land and on-water capture activities, as appropriate. The plan will also discuss hazards of forecasted weather, terrain, and bird species.

Communications Plan

A communications plan for the capture program needs to be part of the site safety plan. The communications plan identifies the method of communication that will be used by the capture team, types of communications equipment (e.g. radios, cell phone), and how the capture program communications will be monitored.

Capture Equipment

An equipment maintenance and inventory schedule is an essential element of a successful bird capture program. Capture equipment and supplies need to be regularly maintained and restocked as necessary to ensure availability, cleanliness/ decontamination, and good working condition when an oil spill occurs. The equipment should be readily accessible and easily mobilized. Staging capture equipment in multiple locations can be helpful in reducing response time.

Capture Technique

An effective capture of oiled birds occurs swiftly with minimal pursuit and noise, uses correct techniques based on the species pursued and local conditions, and exposes the oiled bird to the least amount of stress. Knowing the pursued species' natural history and behavior allows for a more successful capture while decreasing the stress on the birds. Unless specifically authorized by the U.S. Fish and Wildlife Service, no normal, healthy, unoiled birds may be collected. No capture activities may be conducted in pinniped or seabird rookeries. All bird carcasses that are discovered during capture, need to be collected to prevent secondary oiling. Capture teams should receive guidance from the U.S. Fish and Wildlife Service regarding carcass collection protocols and how to record the location and condition of each carcass prior to collection. (See *Dead Oiled, Bird Handling* on page 25). In the case of raptors, only appropriately trained individuals should carry out their capture as these birds require special handling techniques.

The most common capture techniques use dip nets, net guns, and mist nets. Other techniques have been developed to target specific species groups (e.g. the use of foot traps for small shorebirds). The use of spotlights at night is sometimes employed for birds that are especially skittish and difficult to approach during the day.

A capture team consists of two or more people wearing appropriate protective clothing. Capture equipment most likely to be needed should be carried at all times. The teams evaluate each capture site and develop strategies to suit the terrain and species being pursued. Prior to entering the search area, the team identifies a plan of action, keeping in mind that alternative plans and equipment need to be available should the primary plan fail.

Capture by Boat

The first priority in the collection of oiled birds is to deal with birds already beached. Approaching and capturing birds from a boat is considered a secondary strategy. Oiled birds are under stress and should be allowed to come ashore at their own pace. Chasing an oiled bird will use up more of the bird's energy reserves and subject it to further stress. When pursuing birds by boat, it is important to know the birds' diving habits for best capture results. If capture is not accomplished after repeated attempts (3-4) on water, a judgment is made to either back away and hope the bird will beach itself or continue pursuit, which may result in the bird drowning. All personnel working near water must wear personal flotation devices.

Bird Handling

All bird handling should be done in a manner that minimizes stress to the bird and ensures that the bird does not injure itself or the handler. Birds have different weapons and strategies for defense so it is important that oiled birds be handled correctly. The chasing, capturing, and confinement of oiled birds will also increase their susceptibility to secondary and stress-related problems. Use of proper techniques will minimize stress and maximize efficiency. Only authorized, permitted and trained individuals may handle oiled birds.

The Material Safety Data Sheet (MSDS) for the spilled oil should be reviewed prior to handling a contaminated bird. Birds are to be carefully handled through light coverings that minimize damage to the bird's feathers and human exposure to oil. Coverings include sheets, towels and gloves. No oiled birds should be handled with bare hands. Although gloves and coverings are selected to eliminate skin contact with oil and to afford protection from pecks, bites and scratches, heavy or bulky gloves are rarely used and not recommended because they reduce human dexterity and can result in injury to the bird.

Appropriate Bird Handling

- Wear the appropriate personal protective gear, including gloves and eyewear;
- Use a towel, sheet, or light covering to place over the birds;

- Handle clean birds with clean gloves and equipment;
- Be alert for occasional and unexpected sharp foreign objects in birds, such as fish hooks;
- Approach a bird from behind or the side;
- Get control of a bird's head by grasping the beak where it joins the head, by controlling the neck at the base of the skull, or by cupping the skull with a gloved hand if towels and blankets are unavailable;
- Fold the wings into its body and pick it up while controlling the head;
- Hold birds at waist level and away from the face and other people to avoid injury from pecking and biting; and
- Work in teams and request assistance if needed.

NOTE: It is inappropriate to mechanically restrict the bird (e.g., tape, rubber band) from opening its beak/bill.

Appropriate handling techniques are based on the size and species of the bird. For example, small birds, such as shorebirds, are cupped in the hand and placed in small non-plastic, non-abrasive bags (e.g. pillowcase or small cloth bag). The basic technique for medium-sized oiled birds, such as a duck or murre is the two-handed body hold, making sure to not restrict the bird's breathing. Large oiled birds, such as geese, are usually controlled using the buddy system to ensure a proper hold on the bird. References such as *Handling and Restraint of Wild and Domestic Animals* (Fowler, 1995) provide more complete descriptions of bird handling techniques. Aggressive birds will require additional restraint of the head and/or feet and should only be handled by field personnel experienced in such techniques.

NOTE: The handling of raptors should be left to appropriately qualified and experienced personnel.

A summary of bird characteristics, natural history, and species-specific concerns is located in *Appendix 4*.

Containers

Captured birds are immediately placed into containers that provide safety for both the bird and the handlers. These include well-ventilated, solid-sided carriers such as modified cardboard boxes, plastic carriers, or shipping kennels. Containers are constructed to meet the hazards and conditions of transportation. Occasionally, qualified, experienced personnel may elect to use pillowcases as temporary field transport containers for small birds due to difficult terrain/access or weather conditions. All containers must close properly to prevent escape during transport.

Bird container requirements

- Secure lids/tops for closing;
- Sufficient space inside for comfort;
- Paper or cloth towels on the bottom of the container to absorb oil;
- Adequate ventilation on all sides; and
- Labeling to include: date, time, location of capture, species (if known), specific injury, and name of person capturing bird.

Each container should contain only one bird unless determined otherwise by qualified, experienced personnel. If necessary, some gentle, gregarious birds of compatible species (see list below) may be placed two or three to an appropriately sized container.

Compatible Species

Guillemots
Auklets
Murres
Ducks (except Scoters)
Mergansers
Geese
Terns
Sandpipers
Eared Grebes
Horned Grebes

Compatible species placed in the same container should be strong, stable, and equally affected by the oil. Containers are to be checked 5-10 minutes after placing birds together to ensure compatibility.

Steps for Containered Birds

- Pay attention. Do not leave containers with birds unattended;
- Place containers in a safe and quiet location (e.g. away from noise and activity, above high tide-line);
- Minimize temperature extremes (e.g. hot sun);
- Space containers adequately to ensure sufficient ventilation; and
- Keep containers away from oil vapors.

When taking birds to a central collection site or rehabilitation facility, do not leave the birds unattended. Containers are to be handed over to a site worker. Convey to the site worker in writing and orally, information about the bird's condition, the location the bird was found, etc.

Field Stabilization

All of the chemical hazards to humans also apply to affected birds. Attempts by oiled birds to clean their feathers through preening can result in oil ingestion and irritation of sensitive membranes of the eyes, mouth, lungs, and digestive tract. In addition, once feathers become matted, weatherproofing and insulating properties are lost, leading to either rapid chilling or overheating. Other problems may occur when food sources become contaminated, or when birds cannot fly or swim well enough to feed adequately. Despite being on water, oiled birds frequently experience dehydration and electrolyte abnormalities.

Oil contaminated birds that are captured or collected by appropriately trained field teams may require stabilization in the field before being transported to an off-site rehabilitation facility. (See *Training for Bird Rescue/Rehabilitation Personnel*, page 8). Field stabilization is provided to oiled birds that are likely to remain in the field longer than 2-3 hours. Field stabilization is a "first-aid" method, rendered only by trained personnel, for administering temporary care and initial treatment to quickly mitigate the effects of oiling on birds soon after capture. This field treatment will increase the oiled bird's chances for successful cleaning, rehabilitation and eventual release. Field stabilization does **not** include washing or taking blood samples, which can stress the bird and is difficult to accomplish effectively in the field.

Steps For Field Stabilization

- Clear mouth, nostrils and eyes. Heavily oiled birds may have debris and oil built up in their mouths and nostrils, which may impair their breathing. These foreign materials are removed prior to any additional treatment being rendered.

- Regulate temperature. Oiled birds lose their ability to thermoregulate. When possible, the bird's temperature is taken and the bird is warmed or cooled as appropriate. Once a bird's body temperature is normal, the bird is closely monitored for visual signs of chill or overheating.

- Treat for dehydration. Oiled birds are almost always significantly dehydrated and need to be gavage-fed fluids on a regular schedule, beginning at stabilization and as long as presenting conditions do not contra-indicate the administration of oral fluids. Pedialyte®, or a similar electrolyte solution, is recommended for treating dehydration. If the bird will remain in the field for a significantly long period prior to stabilization at a facility, a stomach-coating product (e.g., Toxiban®) may be used to help reduce the long-term effects of ingested oil.

- Minimize stress. Place birds in a safe, quiet, warm, ventilated area away from drafts, human disturbance, and other noises.

- Record field treatments. Transmit treatment records for individual birds, or for groups of birds (when treating large numbers of birds) with the bird(s) when they are checked in at the rehabilitation center.

Dead, Oiled Bird Handling

During an oil spill response, all carcasses need to be collected to prevent secondary oiling. Oiled bird carcasses will be collected in accordance with spill incident-specific instructions and chain-of-custody protocols provided by the U.S. Fish and Wildlife Service. (See *Records*, page 43). The designated, local USFWS representative will coordinate the collection, storage, and handling of any dead migratory birds with the Service's Division of Law Enforcement. When collected, each bird carcass is placed in an individual plastic bag. Where cause-of-death analysis is important, each bird must first be wrapped in clean foil to keep the carcass from contacting the plastic bag, which could contaminate the hydrocarbon sample. Each carcass is labeled with the date, time, location, species (if known), and collector's name; taken to a designated morgue location; and placed in a refrigerated unit.

Bird Transport

Captured birds are moved to an appropriate stabilization or treatment center at the earliest opportunity. Only appropriately trained personnel may transport birds (see *Training for Bird Rescue/Rehabilitation Personnel*, page 8). It is preferable to transport birds in an enclosed vehicle. Adequate space (at least 1-1/2") is left between containers during transport to allow sufficient airflow through side vents (top vents are not, by themselves, adequate). Remember, freshly oiled birds typically emit hydrocarbon vapors; therefore, always maintain adequate ventilation in the vehicle to protect both humans and birds from inhaling such vapors. Only one bird per transport container is acceptable except in the case of non-aggressive, compatible species (e.g. murres), which may be transported two or three birds (same species) to an appropriately sized container (see *Containers*, page 22).

Containers are secured to prevent load shifting that could cause the containers to slide together and impede air circulation. Birds are placed in secured containers before being transported to protect them from injury or escape during the transport process. If birds must be transported in an open vehicle or skiff, it is important that all containers are securely tied with rope or straps prior to transport. Make sure to compensate for cold outside temperatures and wind chill when moving birds in an open vehicle.

Temperature control and monitoring are critical during transport. Wet birds may require a temperature close to 80°F to be comfortable during transport, while dry, oiled birds will require a cooler environment. Note that birds may overheat inside an air-conditioned vehicle when containers are exposed to direct sunlight. Keep in mind that

human comfort during transport may not be synonymous with the temperature and ventilation needs of the transported birds.

Birds are monitored periodically on transports longer than one hour, as directed by the response veterinarian. For trips that take longer than four hours, birds should be hydrated periodically during the transport. Critical cases require more frequent monitoring. The person transporting birds must maintain contact between the field and the rehabilitation facility so that departure and arrival times may be anticipated at these locations.

Summary of Transport Practices

- Allow 1-1/2" between containers for ventilation;
- Only 1 bird per container unless they are non-aggressive compatible species;
- Maintain inside vehicle air temperature between 68-70°F or higher if birds are cold; and
- Monitor birds hourly; more frequently if unstable.

NOTE: No domestic animals are allowed in transport vehicles.

Chapter

5

Stabilization and Rehabilitation

In accordance with 50 CFR 21.31, the U.S. Fish and Wildlife Service issues permits for migratory bird rehabilitation. A rehabilitation permit is required for the capture, care, and treatment of oiled migratory birds. Only those individuals trained and experienced in oil spill response bird stabilization and rehabilitation techniques may care for oiled birds (see *Training for Bird Rescue/Rehabilitation Personnel*, page 8). During an oil spill response, the Incident Command must authorize all bird rehabilitation activities. These activities are developed within the Environmental Unit of the Planning Section of the ICS and implemented within the Wildlife Branch of the Operations Section.

The goal in rehabilitating birds during an oil spill response is the release of a healthy bird back into its natural environment. The stabilization procedures described in this section (similar to those described under "Field Stabilization" in the previous chapter) represent the first medical treatment that an oiled bird receives soon after capture. Only trained and experienced personnel may administer this type of care. Stabilization procedures are performed at a designated stabilization site or at the primary rehabilitation center.

General Guidelines for Stabilization

- Stabilize within 2 to 4 hours of capture.

- Minimize stress. Handle the birds as little as possible. Prepare treatments ahead of time. Keep noise to a minimum. Speak in a low voice. Provide visual barriers or "hides" so that the birds do not have to constantly see humans or other birds.

- Provide appropriate temperature control and ventilation. This is especially important since oiled birds typically have difficulty regulating their body temperature and are susceptible to secondary diseases that can be caused by poor ventilation.

- Evaluate all cases and consider euthanasia of high-risk birds. Unnecessary suffering can be alleviated and limited resources dedicated to those birds having a better chance of survival. (See *Euthanasia* , page 30).

- Prevent health risks to humans and to other birds. Wear protective eyewear, protective clothing, and masks (if appropriate) when handling oiled birds. Isolate birds with signs of infectious disease. Understand the physical dangers associated with the handling of each species. Secure treatment for injured humans, clean all cuts thoroughly with an antiseptic, and obtain medical attention for major wounds.

- Keep complete and accurate records. This helps to ensure that each bird receives appropriate medical care. A sequentially numbered, plastic leg band or equivalent ID tag, should be applied to identify each bird while in care. (See *Records*, page 43).

Federal regulations require a written agreement with a licensed, **veterinarian-of-record** who will provide medical supervision and oversight during a bird-related response (50 CFR 21.31(d)(1)(iii). The veterinarian is responsible for all medical aspects of the capture and treatment program, but does not necessarily have to be physically present during all bird treatment and care actions.

Veterinarian-of-Record Responsibilities

- Joint decision-making with rehabilitation personnel;

- Use of controlled substances (e.g. sedatives, euthanasia);

- Necropsy supervision;

- Triage and pre-release evaluation; and

- Quality of medical records.

Evaluation and Admission

The evaluation and admission process involves collection of biomedical data on individual birds, to establish the medical and rehabilitation courses of action necessary to care for that bird. **All** personnel performing bird evaluation and admission must wear appropriate personal protective equipment to protect them from exposure to oil and potential injury from birds. Additionally, steps should be taken to minimize stress to birds during this process, including speaking in a low voice, and rapid completion of the examination to reduce bird handling time.

When prioritizing multiple birds of the same species, treatment prioritization is based on the nature and extent of oiling, physical examination, and blood parameters. Medical attention should be given to those with the greatest probability of survival.

Four criteria that can be used to establish prognosis are (1) packed cell volume (PCV)/total solids (TS) determinations, (2) body weight relative to norm for species, (3) body temperature, and (4) physical exam results. Birds that do not meet criteria set for these results may be quickly, and humanely euthanized in order to alleviate suffering and to allow more treatable birds a greater opportunity of rehabilitation success.

However, when multiple species are presented for triage, prioritization by species may also be necessary. For example, an endangered species or a species of special concern may be given priority over resident waterfowl or an exotic species with the same or more critical condition. The incident-specific wildlife recovery and rehabilitation plan addresses species prioritization, as an integrated parameter of triage. The designated U.S. Fish and Wildlife Service representative establishes the species prioritization in close consultation with the veterinarian-of-record.

General Steps for Evaluation and Admission

- Start an individual record for each bird.
- Review and record bird data provided by field team: capture location, date, time, chain-of-custody information.
- Place a temporary identification band or tag on each bird.
- Record general bird information: ID number, species, age class, sex (if possible).
- Record overall impression of bird's clinical status (e.g. depressed, hyperactive, alert, etc.).
- Record degree of oiling: area(s) of body and degree (light, etc.).
- Perform physical examination: record temperature, weight, presence of overt injuries/disease states, oil-related effects, etc.
- Perform stabilization treatment: manually remove excess oil from nares, mouth and vent; flush eyes with a sterile saline or equivalent solution; and administer Pepto-Bismol® or Toxiban® or their equivalents in conjunction with hydration using a balanced electrolyte solution.
- Collect samples: take a blood sample to determine packed cell volume (PCV), total solids (TS) and blood glucose (BG); an oiled feather sample; a photograph of the bird (for evidentiary purposes); and other specialized samples for additional biomedical diagnostics, as indicated.

Additional medical therapies that may be warranted

- Parenteral (e.g., not oral) fluid administration.
- Prophylactic use of antifungals (e.g., itraconazole).
- Start of treatment/isolation for overt clinical disease or injuries.
- Start of treatment addressing hematological abnormalities.
- Treatment of vomiting and/or seizures.
- Initiation of additional diagnostics when indicated (e.g. blood panels/CBC's, radiographs, or cultures).

Inappropriate Treatments During Admission

- Prophylactic use of antibiotics, eye ointments, or antiparasitics in the absence of clinical signs.
- Oral administration of mineral oil.
- Washing bird immediately after initial evaluation and admission.

Euthanasia

During an oil spill response, there are circumstances under which it may be necessary to humanely euthanize birds. For each spill where bird rehabilitation is undertaken, the bird rehabilitator will prepare a written euthanasia plan in consultation with the veterinarian-of-record and the designated U.S. Fish and Wildlife Service representative. The euthanasia plan will take into account species, spill, and regional characteristics.

Euthanasia is appropriate for any oiled bird with injuries that will render it unable to survive in the wild or unsuitable for use in captivity (50 CFR 21.31(e)(4)(iii)). Such injuries include fractured limbs (particularly those affecting a joint), injuries to the beak, extensive soft tissue injuries, and significant visual or auditory deficits. If birds are euthanized in the field, they will be collected following the procedures outlined in this document in Chapter 4. To prevent secondary contamination or poisoning, euthanized carcasses are never left in the field.

See *Appendix 5*.

Necropsy

Valuable information can be collected from necropsies of dead birds. This information can be used both to refine treatment protocols for live birds during the spill event as

well as to collect data on the successes and limitations of the rehabilitation process. The spill response veterinarian-of-record should conduct or supervise all necropsies, in consultation with the designated representative of the U.S. Fish and Wildlife Service. Prior to conducting a necropsy, the USFWS representative and veterinarian will agree on which forms to use; which samples to collect (e.g., tissues, feathers); how those samples will be prepared (e.g., formalin or frozen), stored, and shipped; and where samples will be analyzed. Reports are filed and all samples handled and stored using appropriate chain-of-custody protocols, provided by the USFWS.

Cleaning

The structure of a bird's feathers provides insulation and waterproofing. When a bird is oiled, waterproofing and insulation are lost, which may lead to hypothermia. Internal effects of oil may include damage to the lungs, gastrointestinal-hematological system, liver, or kidneys. This damage is caused by inhalation of volatile components, ingestion during preening, drinking or eating, and dehydration.

Based on these injuries, birds must be medically stabilized before cleaning. The cleaning process can be stressful to birds and care should be taken at every step to reduce that stress. Birds are monitored for signs of stress or instability during the wash, rinse, and drying processes. Handlers must always work in teams when handling birds during the cleaning process.

Bird Health Criteria for Cleaning

- Bright/Alert/Responsive (BAR); judged stable.
- Packed cell volume (PCV) and total solids (TS) within 90% of normal values.
- Exceptions as determined by veterinarian on a case-by-case basis.

Wash Water Criteria

- Pressurized and adjustable system delivery at 40-60 psi.
- Temperature 102 to 108°F depending on species, type of oil, and condition of the bird.
- Hardness 2-5 grains per gallon (some variation in species requirements).
- Large volumes of water (with these characteristics) available.

Cleaning-agent Criteria

- Able to remove oil from feathers without damaging feather structure or irritating skin and mucosal surfaces.
- Non-toxic.

- Leaves no residue.

NOTE: The only bird-cleaning agent that is recommended at this time is Dawn® dishwashing liquid (regular, not anti-bacterial formula) because it removes oil from feathers; is non-toxic; and does not leave a residue. Other methods or products are not recommended for use or testing during an oil spill at this time.

NOTE: Pretreatment agents are used only when absolutely necessary because they are an additional substance that must be removed. Methyloleate or warmed Canola oil are appropriate agents for pre-treatment of tarry feathers.

Drying

The most effective means of drying most bird species is to maintain an ambient air temperature between 90 to 95°F using a pet dryer. Other heat sources, such as heat lamps or brooders, may be more appropriate for some species including most shorebirds. Birds are continually monitored during the drying process to ensure that they do not become overheated. Using net-bottom pens for most water birds will reduce the chances of overheating and allow for better circulation of warm air to ventral (belly) feathers. Some species (e.g. eagles, pelicans), however, require the use of pens with solid floors.

Waterproofing (water birds)

After water birds (e.g. ducks, murres) are washed and determined to be dry or waterproofed, they are given access to freshwater pools for swimming. Birds are checked regularly to monitor for chilling and incomplete waterproofing. A seabird is considered "waterproofed" if it exhibits normal behavior, body temperature, and buoyancy after 24 hours in a pool with no haul-out. Some reasons for a lack of proper waterproofing may include incomplete removal of oil, incomplete or non-optimal rinsing, underlying injury or disease, poor pool-water quality, and feather loss or damage.

Waterproofing (terrestrial and wading birds)

After a terrestrial or wading bird is washed and determined to be dry or waterproofed, it is given access to fresh water for drinking and bathing. Additionally, misting the bird will encourage preening and test for waterproofing. Terrestrial birds should display waterproofing appropriate for their species.

Husbandry

Husbandry encompasses the housing, hygiene and nutritional aspects of maintaining wild birds in captivity. The goal in rehabilitating oiled birds is the release of healthy birds back into their natural environment. In order to achieve this goal, it is necessary

to treat the presenting problem — injury from oiling — as well as to prevent any secondary infections or injuries that may occur while keeping birds in captivity. The key to quality husbandry during an oil spill response is an emphasis on herd-health management.

Housing

Injuries or illnesses from improper captive housing can be a serious problem in the rehabilitation of oiled birds. Appropriate housing can reduce or prevent problems such as pressure sores, feather contamination, foot lesions, and infectious disease transmission. The following are best practices guidelines for good housing design and maintenance to maximize the chances of survival and release of healthy birds:

- Construct pens according to the needs of the species affected.
- Allow appropriate space based on species need.
- Provide padding as necessary.
- Avoid cages with wire walls or floors as these can cause feather damage, beak trauma, and foot lesions.
- Avoid solid floors for species susceptible to keel sores or fecal contamination of feathers.
- Provide perches as required.
- Provide for an adequate thermal gradient (combination of ambient air temperature and radiant heat source) appropriate for birds to maintain normal body temperature.
- Avoid placing washed (clean) birds in housing that previously held oiled (contaminated) birds to minimize the risk of re-oiling clean birds.
- Maintain high water quality through water exchange or overflow to eliminate waterproofing problems by re-contaminating feathers.
- Provide haul-outs as required, taking into account waterproofing and pre-release condition.

Disinfecting

Prevention of disease transmission relies heavily on effective disinfecting and sterilization of all inert objects used in treating the birds. In addition, consistency in technique and frequency of cleaning procedures will help ensure that optimum cleanliness is maintained throughout the response effort. Personnel should be trained in standard cleaning procedures so that these procedures will become routine.

Some Important Disinfecting Guidelines

- Know which pathogens are likely to occur; match disinfectant agents and procedures for best results.
- Clean and disinfect transport cages, holding pens, and restraint equipment after each use. Outdoor steam-cleaning is the preferred cleaning method.
- Change the papers under net-bottom pens at least twice a day.
- Complete water turnover, at least every 4 hours, to provide the most effective water filtration or overflow in pools.

Nutrition

Birds are fed sufficient food to increase body weight. Sufficiency is determined by the nutritional value of the food, based on a metabolic formula as well as the underlying body condition and health status of the bird.

Nutritional and Food-Handling Guidelines

- Food Types and Delivery: In most cases, gavage-feed birds a high-caloric and digestible food slurry prior to washing. For cleaned birds, provide solid food, appropriate for the species, in dishes or containers in a manner that prevents re-soiling of feathers. Feed birds, within pools, non-oily food in a manner that mimics feeding in their natural environment. Allow all birds, within an enclosure or pool, an opportunity to feed. Keep feeding records for each bird, or pen of birds in the case of large numbers of birds.
- Cleanliness: Wash hands prior to, and after, handling food. Thoroughly clean and disinfect all food preparation utensils and containers after each use.
- Storage: Properly store all food in freezers, refrigerators, airtight containers, etc. to prevent contamination and spoiling. Store bird and human food separately. Monitor temperatures of refrigerators, freezers, thawing tubs and food handing areas to ensure food quality.

Ongoing Health Assessment

After washing, bird assessment must continue to determine whether additional medical and rehabilitation intervention is necessary prior to a release assessment. These procedures, while not as intensively instituted as during intake, follow the same basic areas: assessment of hematological values (PCV, TS), assessment of nutritional state (through successive weighing and assessment of flesh tone), and behavioral observations in pools or pens (to ensure appropriate feeding activities, social interactions, waterproofing, and other behaviors). All birds are handled either with washed hands or powder-free gloves (to maintain waterproofing status), and only non-contaminated exam equipment and areas are used for these assessments. Additional

pre-release rehabilitative care may be necessary for some individuals and, if birds need to be kept in a hospital situation for a period of time, rewashing may be necessary.

Chapter

6

Facility Requirements

The size and extent of a rehabilitation facility will vary depending on location and need. Not all spill responses will require the use of, or will be in the vicinity of a permanent bird rehabilitation facility. The size of the spill, its location, and the number of birds oiled will determine the type and location of a facility that can meet the required need. There are basically, three types of oiled bird rehabilitation facilities: fixed, permanent facility; temporary facility established in local, fixed structures; and mobile units brought to a spill location to set up a temporary facility.

The facility requirements in 50 CFR 21.31 establish minimal standards of care. It is critical that spill responders and pre-spill planners recognize the degree of effort and complexity required to implement a migratory bird response and establish an adequate facility. Pre-spill planning is encouraged to achieve wildlife response systems that will adequately address the needs of small as well as large bird-rescue efforts. For best achievable care standards, response entities who are planning or authorizing oiled-bird rehabilitation facilities are encouraged to consult: (1) entities who have constructed permanent facilities, operated temporary facilities, or who have conducted facility planning (e.g., OWCN/IBRRC, Washington State, Tri-State Bird Rescue and Research, Inc.); and (2) documents such as the States/British Columbia Oil Spill Task Force wildlife facilities report.

Regardless of the type of facility used for bird rehabilitation during a spill response, the following facility requirement guidelines apply:

Facility Setup

- Establish and operate intake, holding, and isolation areas within 24 hours of wildlife response activation.

- Establish and operate bird cleaning and pre-release areas within 48 hours of wildlife response activation.

Facility Layout (traffic flow)

- Separate contaminated and uncontaminated areas with a de-contamination area, to eliminate cross-contamination from oil and disease.

- Ensure that facility layout minimizes audio and visual stimulus (e.g., human traffic and noise) to reduce stress to birds.

- Ensure that layout facilitates the natural "flow" of birds through the admission, rehabilitation, and release process.

Established Bird Areas (within a Facility)

- Intake
- Holding
- Wash/rinse
- Drying
- Pools/Outdoor caging
- Food preparation
- Hospital/isolation
- Morgue/necropsy
- Storage

In certain situations and depending on the spill characteristics, areas may have multiple designations, i.e., intake may need to occur in the holding area, but such designations will still follow the above indicated "traffic flow" requirements.

NOTE: A general guideline for estimating sufficient space for the bird holding area within a facility, including walking and aisle space, is to allow for 6 square feet per average-sized (1 kg) bird. More space may be needed for larger birds.

Facility Temperature

- Maintain air temperature between 65-85°F, adjustable within 2°F increments, in all pre-wash and wash areas, including bird intake, holding, and hospital.

- Maintain ability to warm or cool individual bird enclosures as needed.

- Maintain temperature in all remaining areas to meet human comfort needs.

Air/Ventilation

- Provide fresh air exchanges via air/ventilation system that ensures healthful air quality (as indicated by low odor levels, prevention of mold/mildew

growth, and minimal dust particles). Use of HEPA filters is highly recommended.

- Optimal: In bird areas, a minimum of 10 to 15 air exchanges per hour, to minimize disease risk.

- Optimal: In human areas, a minimum of 8 air exchanges per hour.

Electricity

- Maintain a reliable electrical supply sufficient for all electrical needs including heating, lighting, ventilation, air conditioning, water heaters, pet dryers, heat lamps, blenders, freezers, refrigerators, pool filters, computers, and faxes.

- Provide Ground Fault Interrupt circuits in all areas where circuits may be exposed to water.

Water Supply

- Temperature: Provide washing and rinsing water temperatures of 102 to 108°F, while maintaining additional hot water supply sufficient for other uses (e.g., laundry, cleaning, food preparation, warm-water pools).

- Pressure: Provide water pressure at 40-60 psi in wash and rinse area, while maintaining sufficient water pressure in other areas (e.g., doing laundry, washing dishes).

- Quantity: Provide supply line(s) large enough for all areas requiring water simultaneously (e.g., wash/rinse area, pool area, laundry.) The quantity should be sufficient to provide a continuous flow of 4 gallons/minute to all indoor outlets and additional supply for pools.

- Quality: Maintain a water hardness of 2-5 grains per gallon for all bird wash and rinse stations and waterproofing pools. Provide a source of potable water for human use.

Waste Water

- Facilitate disposal of all oily wastewater in accordance with appropriate Federal, State, and municipal regulations.

- Facilitate disposal of all gray water (e.g., rinse water, pool overflow) in accordance with appropriate Federal, State, and municipal regulations.

- Control storm water and other runoff, as appropriate, to prevent contact with gray water and oily wastewater.

Solid Waste

- Facilitate disposal of all solid waste in accordance with appropriate Federal, State, and/or local hazardous waste, municipal solid waste, and/or biological waste laws and regulations.

- Ensure that disposal of carcasses proceeds under the direction of the designated U.S. Fish and Wildlife Service representative.

Outdoor Areas

- Maintain a perimeter of restricted access from the public to outdoor areas.

- Provide outdoor space typically as large as the footprint of the facility itself (buildings or structures); may be larger depending on the species.

- Provide sufficient pool size as dictated by release criteria and by species (e.g., to demonstrate that grebes can fly, flight space is provided within the outdoor enclosure).

- Locate facility in a place that minimizes visual and auditory stress to birds.

- Provide vehicle access and parking.

Non-Bird Areas

- De-contamination area.

- Administration area (e.g., sign in, volunteer orientation, training, record keeping).

- Rest areas and rest rooms for workers.

- Sufficient space for human food storage, preparation, and dining.

Security

- Provide controlled access to the facility and any associated outdoor areas (e.g., pools, bird enclosures).

Pest Control

- Develop and maintain a pest control plan for rodents and insects.

- Develop and maintain a plan for predator exclusion.

Communications

- Ensure adequate access to phones, faxes, and computers with internet access for all rehabilitation personnel.

- Maintain communication, via radio or cell phone, with all field capture teams and field stabilization units.

Visitor Control

- Coordinate and facilitate all visits by news media through the Joint Information Center within the ICS.
- Limit visitor frequency to no more than 2 per day.
- Limit number of persons per visit to minimize stress to birds.

Chapter

7

Release

Release Criteria

The goal in rehabilitating oiled birds is to release healthy birds back into their natural environment. During a spill event, it is highly recommended that the bird rehabilitator prepare a release plan for the release of rehabilitated birds in consultation with the designated USFWS representative. The plan is submitted to the Planning Section within the ICS and authorized by the Incident Command. There are certain criteria that must be met prior to releasing birds. For those birds that do not meet release criteria, several options are available following consultation with the USFWS. These include additional rehabilitation, euthanasia, or placement in a long-term facility.

Bird Release Criteria

- Normal behavior (including natural feeding, swimming, & diving);
- Body weight within 10% of normal for that species;
- Waterproofed;
- Normal blood values;
- Normal physical exam;
- Free of apparent disease;
- Acclimated to outdoor temperature and light;
- Pelagic species who have been maintained on fresh water for over 14 days should be re-acclimated to salt water prior to release; and
- Free of all temporary leg bands and other ID tags and fitted with a permanent USFWS metal leg band.

Release Site Criteria

- No oil contamination present;

- No risk of re-contamination;
- Same general geographic area of capture, if possible;
- Appropriate seasonal range for species (important consideration during migration periods);
- Available, natural, uncontaminated food sources;
- Minimal human disturbance (e.g., boats, noise);
- Favorable weather conditions/forecast;
- Appropriate time of day for species; and
- Minimal logistics for traveling to site.

Post-Release Monitoring

To determine the long-term effectiveness of rehabilitation of oiled birds, post-release monitoring is a necessary component of the rehabilitation effort. Follow-up on released birds can improve the processes and criteria associated with emergency bird care. Monitoring also enhances biologists' understanding of the role that exposure to oil has on both medical and behavioral aspects to bird ecology, such as short-term and long-term survival and breeding status. A post-release monitoring plan should be part of the USFWS-approved release plan.

Several different methods are currently used for post-release monitoring of birds after rehabilitation. The most commonly used technique is to acquire federal band return data, collected by hunters, beach walk programs, or others, to determine mortality levels in released birds. Although this method is relatively simple to undertake, it is difficult to determine survival with any confidence due to low band return rates. A method that facilitates collection of more behavioral information is color banding and visual observation of released animals. This method requires large amounts of observation effort and is limited to birds that remain close to land and do not migrate. The most effective means to acquire information on released oil rehabilitated birds is through the use of radiotelemetry. This method involves placing a transmitter onto birds prior to release and monitoring the activated signal by radio or satellite. In this way, biologists may follow birds for months to years after release.

Chapter

8

Records

The importance of recording information cannot be over-emphasized. Record collection enhances individual bird care, response evaluations, and the ability to accurately characterize the best practices for appropriate care. In-house records are maintained at the rehabilitation facility and copies provided to the U.S. Fish and Wildlife Service. Final reports from the rehabilitator for the oiled-bird response, including carcass chain-of-custody and sample collection records, where required, should be delivered to the USFWS within 30 days of the date the FOSC declares the response closed or from the departure date of the rescue/rehabilitation organization, whichever comes first.

Scientific Records

The following types of records are necessary to preserve vital information for scientific study, natural resource damage assessment, and improved rehabilitation practices and techniques:

- Resources-at-Risk Survey: provides information regarding the location of birds and other animals in relation to the spilled oil.
- Oiled bird sightings: records and maps for all reports of oiled birds.
- Field Retrieval Report: records for all birds collected in field.
- Live Bird Log.
- Dead Bird Log.
- Running tally: list of all in-house birds by species and case number.
- Daily Care Report: documents care for each bird or enclosure, including feedings, treatments, medications, normal/abnormal activities.
- End-of-Day Report: reports current and next day's work.

- Oiled Bird Examination Report: individual record summary of retrieval, medical exam, diagnostic results, samples collected (chemical, blood, and tissue), cleaning, treatment, evaluation, chain-of-custody, Federal bird bands, and final disposition.

- Record of samples collected (chemical, blood, feather, and tissue).

- Lab Analyses Report: identifies all samples sent to labs; requested analyses; and lab results.

- Federal Bird Banding Report: lists all birds banded for release.

- Necropsy Report.

Some sample forms are provided in *Appendix 6.*

Administrative Records

The following are types of additional documentation and reporting requirements associated with an oil spill response effort for entities such as the Incident Command System, USFWS Rehabilitation Permit Office of Migratory Bird Management, and law enforcement, among others.

- Incident Action Plan – ICS 200: Includes Site Safety and Health Plan, Communications Plan, Organizational Structure, and Group Assignments.

- Pollution Incident Daily Resource Report (USCG Daily Report).

- Chain-of-Custody Record: all migratory birds that die as a result of contact with exposed oil represent evidence of a potential violation of the Migratory Bird Treaty Act. As such, each bird carcass must be labeled with an *Evidence Seizure Tag* provided by the USFWS Division of Law Enforcement or other law enforcement agency, through the designated USFWS representative. The bird carcasses are then delivered to a central, secure, evidence storage area and a Chain-of-Custody record completed.

- Qualified Wildlife Responder Application.

Some sample administrative record forms are provided in *Appendix 6.*

Appendices

Appendix 1. Sample Supply and Materials List

Administration/Communications Items:

No.	Item	Purchase (P) or Stockpile (S)
	Air horn	P
	Animal identification and natural history books	P
	Beepers	P
	Binoculars	P
	Cellular phones	P
	Chairs, folding or stacking	S
	First Aid Kit (humans)	P
	Food and fluids for volunteers geared to good nutrition and hydration (from a list of local sources prepared in advance)	P
	Maps of impacted area and response facilities	P
	Marine radios (handheld)	P
	Master copies of all forms (designed in advance)	P
	MSDS binder (add pertinent sheets as needed)	S
	Operations Manual (designed in advance)	S

Animal Care Items:

No.	Item	Purchase (P) or Stockpile (S)
	Aluminum foil	P
	Antiseptic solution (Povidone iodine; chlorhexidine)	P
	Aprons (full coverage vinyl)	S
	Astro-Bubble® bedding roll	S
	Barrier Cream	S
	Bleach	S
	Blender, industrial type	S
	Blood collection tubes: Red top ____ Lavender top____ Green top ____ other types _____	P
	Boots, 16” vinyl (Men’s sizes 5-12)	S
	Broad spectrum antibiotic (having wide safety margin)	P
	Brood Rite® heaters 240 500 750 watt units	S
	Buckets, 5 gallon	P
	Butterfly catheters--Pediatric size or Scalp vein sizes	P
	Camera, disposable (to record each animal on intake)	P
	Can opener	P
	Cardiac and respiratory stimulants	P
	Catch pole	S
	Centrifuge for hematocrit tubes	P
	Clay tray for hematocrit tubes	P
	Cleaning table--sturdy, stable, and water resistant (96”x30”x28“)	S
	Cloth tape	P
	Clothes pins	S

	Cotton balls	P
	Cotton swabs	P
	Culturettes	P
	Cutting board	S
	Dawn® dishwashing liquid	S
	Dexamethasone sodium succinate	P
	Diaper pins	S
	Digital gram scale	P
	Dish drainer mat (perforated)	S
	Dishpans, plastic	S
	Disinfectant (Roccal D®)	P
	Drum lid wrench	P
	Drums, 55 gallon with lids	P
	Elasticon® tape	P
	Electrical adapters (heavy duty, triple outlet, outdoor type)	S
	Enteric coating agent (i.e. Pepto-Bismol® or Toxiban®)	P
	Euthanasia solution	P
	Exam forms	P
	Exam Tables Size:	S
	Eye wash bottles	P
	Floatation vest	S
	Floor mats, non-slip, self draining, anti-fatigue	S
	Foley catheters (12-16 gauge, with adapters) (12 adapters and 30 catheters per dozen animals)	P
	Food processor	S
	Food strainers	S
	Food/water containers Size(s):	S
	Formalin 10%	P
	Galvanized tubs, 17 gallon round, with lids	S
	Garbage can, 33 gal. metal with lid & wheels (rodent proof food storage)	S
	Garden hose (25')	S
	Gauntlet style gloves, butyl or neoprene	S
	Gauze squares	P
	Heat lamp fixtures with inline switch, clamp on type	S
	Heat lamps, 150 watt conical ceramic type	S
	Heating mats, kennel type	S
	Hematocrit tubes	P
	HEPA filtration units (portable)	P
	Hot/Cold water mixing valves, accurate +/- 2^{o}F.	S
	Injectable anesthetic agents	P
	Injectable sodium bicarbonate	P
	Insect repellent	P
	Isopropyl Alcohol	P
	IV fluid stand	P
	IV sets (18-25 gauge) Sizes:	P

	Kling® gauze	P
	Knife sharpener	S
	Knives carving paring boning fillet	S
	KY jelly	P
	Leg bands, plastic, numbered Sizes:_____ Colors: red blue yellow green white other____	P
	Lights, portable, on stand	S
	Measuring cups and spoons	S
	Micropore® tape	P
	Microscope	P
	Microscope slide cover slips	P
	Microscope slides	P
	Milk crate, plastic	S
	Multiple animal feeder	S
	Multitest sticks	P
	Necropsy instruments (append list)	P
	Needles (hypodermic) Sizes:	P
	Net, cast	S
	Net, hand	S
	Net, hoop	S
	Net, long handled	S
	Non-steroidal ophthalmic antibiotic solution	P
	Nylon netting (rolls 0.5” to 1”, smooth mesh)	S
	Oral rehydration fluid (i.e. Pedialyte®)	P
	Panalog® cream	P
	Penlight	P
	Perching and flooring material Type:	P
	Peroxide	P
	Pet carriers, waxed cardboard Small Large	P
	Pet carriers, plastic Large Medium	P
	Pet dryers, portable	P
	Plastic cups	P
	Plastic pitchers pint quart gallon	S
	Plastic sheeting, 4-8 mil polyethelene, 8’x100’ rolls	S
	Plastic Totes (small to large) for food storage	S
	Play pens, soft sided	S
	Plumbing adapters from 1/2” shower head to garden hose	S
	Pool thermometers	S
	Poultry shears	S
	Pretreatment agents (if needed based on type of oil and species involved)	P
	Protective goggles (non fogging)	S
	Pump hoses for intake and output, hot water resistant	S
	Rain gear XXL XL L M	S
	Raptor or welders gloves	S

	Refractometer (temperature compensated)	P
	Sea salt (bags and tablets)	P
	Sharps container	P
	Sheets	S
	Shell or crab cracking mallet	S
	Shelving unit (water resistant, sturdy)	S
	Shower heads w/inline shut off valves	S
	Sponges	S
	Spray/mist bottles, quart size	S
	Sterile electrolyte (Lactated Ringers Solution with 2.5% Dextrose; or Normosol)	P
	Sterile gauze wrap Size:	P
	Sterile instruments (list appended)	P
	Sterile saline	P
	Sterile syringes, Catheter tip Sizes:	P
	Sterile syringes, Luer lock type (1cc-60cc) Sizes:	P
	Stethoscope	P
	Stool	P
	Sump pumps (1/4 HP for small pool drainage)	P
	Sunscreen lotion	P
	Surgical gloves XL L M S	P
	Surgical masks	P
	Survival suit	S
	Tegaderm® Skin Covering	P
	Telfa® Pads	P

Appendix 3. Deterrent Techniques

Gas-Operated Exploders

Detonators consist of a bottled gas supply, separate pressure and combustion chambers, an igniting mechanism and a barrel to aim and magnify the blast. Gas-operated exploders produce a loud directional shotgun-like noise by slowly filling a bellows with propane gas from a tank, then rapidly transferring this gas to a firing chamber and igniting it with a spark. Blasts are emitted at adjustable time intervals. The interval between detonations can be varied from less than one minute to 30 minutes. Some gas-operated exploders can be set to fire at random intervals and rotate after each explosion so that subsequent shots are aimed in different directions. The sound level is approximately 120 dB. An exploder can operate for about two weeks without refueling, but needs to be maintained regularly for effectiveness and to ensure that it is working properly.

> Note: Gas-operated exploders are extremely dangerous and should be used only by trained personnel.

Advantages

- Deployable in onshore and offshore situations (when placed on anchored rafts) especially when the oil is well confined and where birds are particularly susceptible;
- Protective of relatively large areas (200 - 1000 m or 30 - 50 ha);
- Rapidly remobilized;
- Automatically operated and require only minimal staffing;
- Effective during both day and night;
- Especially effective in deterring dabblers and geese;
- Inexpensive to operate and require little maintenance;
- Inexpensive to purchase ($300); and
- Widely available.

Disadvantages

- Birds rapidly habituate to the sound of the blasts (no more than two or three days and sometimes less than a few hours for some bird species);
- Not effective in deterring most shorebird species as well as gulls, coots, grebes and loons;
- Significantly reduced effective range and sound intensity when used in fog and wind;
- Difficult to install and operate on an anchored raft in open water and in bad weather; and
- Disturbing to local residents and responders.

Pyrotechnics

These devices frighten birds by producing a whistling noise, explosion and/or flash of light. Types include shotgun-launched projectiles (shell crackers) and a variety of pistol-launched projectiles. When using pyrotechnics, the danger of igniting spilled oil and vegetation should always be avoided. Both shotgun- and pistol-launched devices should be fired with the wind, and away from personnel. Safety goggles and ear protectors (muff or ear plug type) are worn, and personnel using pyrotechnics are expected to be trained in firearms safety.

Shotgun-launched projectiles include shell crackers and scare cartridges. They are fired from a 12-guage shotgun with the shell shot being replaced by a bulldog or M-80 firecracker that explodes at 100-150 yards

(91-136 m). Single barrel shotguns that break and load at the breech are recommended. The shotgun should be fired from the hip at a 45° angle, and shell crackers should explode as close to the birds as possible. Because of the light charge, the shotgun has only a slight recoil.

> Note: Pyrotechnics are extremely dangerous and should be used only by trained personnel.

Advantages

- Effective both day and night;
- Easily directed close to water birds;
- Especially effective in deterring open-water birds;
- Relatively high radius of effectiveness (at least 200 m from the source and up to 1 km for some bird species);
- Effective on land or in offshore situations;
- Highly effective in combination with other deterrents (motorboats, ATV, effigies); and
- Relatively inexpensive (roughly $50 per hundred).

Disadvantages

- Short duration of effectiveness (one or two hours);
- Less effective in deterring dabbling ducks;
- Ineffective in deterring gulls and shorebirds;
- Significantly reduced effective range and sound intensity when used in windy situations;
- Requires continuous staffing;
- Potentially hazardous to operators and bystanders if not used carefully;
- Potentially hazardous if used in areas containing volatile oil components; and
- Disturbing to local residents and responders.

Aircraft

Aircraft, especially helicopters, are effective deterrents because of the combination of loud noise and rapid approach from above. They are often effective for hazing birds away from large areas. Helicopters may also be used to herd flightless (young and molting) birds.

Aircraft are considered to be especially useful during the early stages of cleanup and hazing operations. They are more effective if used in combination with other devices such as shell crackers and gas-operated exploders. Because of their maneuverability and noise, helicopters are probably more effective than fixed-wing aircraft.

Not all bird species will take flight in response to overhead disturbances. Some waterbirds (e.g., loons and alcids) dive rather than fly when approached by aircraft, and others who are young or in their molting or brood-rearing stage may be incapable of flight. Flightless birds can be herded with a helicopter (Alaska Regional Response Team, 1991), or ground patrols after the helicopter has departed. Helicopters have been used successfully to drive flightless Canada geese over water, exposed tidal flats, and dense sedge in Alaska with the helicopter remaining 10 to 20 m (33-66 ft) behind the geese at an altitude of 1-15 m (3-49 ft). (Timm and Bromley, 1976).

Advantages

- Readily available to remote and roadless areas;
- Disperses birds in different types of habitats (marsh birds, offshore birds);
- Rapidly disperses birds while oil is still offshore;
- Requires minimal staffing; and
- Highly effective at deterring geese.

Disadvantages

- Less effective at deterring species other than geese, especially during molt;
- Less effective for birds gathered in very attractive sites like feeding or nesting grounds;
- Increased potential of bird-aircraft collisions during low flying activities;
- Ineffective at night;
- Reduced or limited feasibility during bad weather (especially fog);
- Time consuming for deterring birds on a large scale basis;
- Limited ability to procure helicopters, in heavy demand during an oil spill; and
- Relatively high cost of charter aircraft.

Motorboats

Motorboats can be used to deter birds located offshore where hazing from the shoreline with other techniques is ineffective in driving birds away. A few studies conducted during the last 20 years have demonstrated the potential of boats as an effective deterrent. Birds are more sensitive to boats propelled by outboard motors. A powerboat causes virtually instantaneous flight as soon as it appears on the water, causing a majority of birds to leave. There is some speculation that the larger the flock, the more sensitive it is to an approach (Batten, 1977). The hazing of diving birds with boats is generally considered slow, labor intensive, and may be ineffective. Boats may be useful for herding flightless waterfowl away from spilled oil to boomed areas of lagoons, or overland to inland lakes (Alaska Regional Response Team, 1991).

Advantages

- Useful in deterring birds located at some distance from the shoreline;
- Rapidly implemented for deterring birds while oil is still offshore;
- Works well with most species except diving birds;
- Covers relatively large areas; and
- Requires limited staffing.

Disadvantages

- Deployment potentially hazardous during bad weather, ice conditions or darkness;
- Limited ability to locate birds, especially in rough seas; and
- Difficult to direct dispersed birds to unoiled waters.

All-Terrain Vehicles (ATVs)

All-Terrain Vehicles (ATVs) such as quad-runners are moderately effective for hazing many species of waterfowl and shorebirds. Human presence reinforces the effects of the noise and rapid movement of the vehicle. A quad-runner can also be equipped with air horns or sirens, or used with pyrotechnics.

Advantages
- More efficient for covering larger shore areas (between 3 and 5 km instead of 1-2 km by foot); and
- Most effective when used in combination with other methods (e.g. noisemakers).

Disadvantages
- Limited to birds onshore;
- Limited to daylight use; and
- Potentially destructive to certain habitat types.

Electronic Sound Generators

These devices, broadcast loud, intermittent electronically synthesized sounds that are in the audible range of birds. The units can be adjusted to the most effective range of sound patterns for the target bird species, and sound patterns within this range can be varied over time to decrease habituation. Sound generators can be positioned on land, mounted on boats, or housed within a raft or buoy for effectiveness in open water and marine situations.

Advantages
- Useful in open water environments;
- Rapidly deployed;
- Projects over large areas;
- Readily deployed on leading edge of drifting oil slick;
- Maximizes potential of dispersing birds away from contamination, when deployed directly into oil slick;
- Reduces potential of bird habituation because buoy is moving with the wind and current and regularly encounters new groups of birds;
- Limited habituation of birds, even when anchored, due to the diversity of sounds produced;
- Operable and effective day and night;
- Operable during bad weather (fog and rain);
- Readily retrievable;
- Easy to handle and operate by two persons;
- Constructed to withstand the hazards of fire and explosion sometimes associated with oil slicks;
- Long-lasting effectiveness (>two weeks);
- Low maintenance (requires four marine batteries: two in the unit and two on full charge).

Disadvantages
- May be less efficient in areas where birds are accustomed to loud background noises, where hunting pressure is low; or where birds congregate in very secure habitats;
- Batteries must be replaced or recharged after 72 hours of operation;
- Requires a boat or a helicopter to be deployed offshore;
- Regular monitoring (daily) is recommended to ensure effectiveness;
- Range of effectiveness decreases during high winds and rough seas;
- Requires monitoring, when used in oil slick, to ensure that device stays in oil slick;
- Duration of effectiveness unknown when the buoy is used in a stationary mode;
- Disturbing to local residents and responders;

- Expensive, more so if the costs of radio beacon transmitters and receivers are included; and
- May not be immediately available.

Biosonics

These techniques use distress, warning, or alarm calls that are broadcast by tape players to disperse single or closely related species from the immediate area. In general, individuals or small flocks are less responsive than large flocks. The effectiveness of biosonics can be increased by supplementation with pyrotechnics.

Advantages

- Effective at lower sound intensities; and
- Slower habituation.

Disadvantages

- Highly species specific;
- May attract rather than deter birds, depending on life stage; and
- May attract predators and scavengers.

Underwater Acoustics

These include devices that put sound into water, such as sweep frequencies, killer whale vocalizations, and underwater percussion devices. These devices have not been studied enough to allow for guidance or to determine advantages and disadvantages and, therefore, are NOT recommended for use as bird deterrents during oil spill response.

Balloons

All-weather helium balloons are considered effective if properly maintained and frequently refilled and repositioned. They are generally 20-30 inches (50-75 cm) in diameter, and should not be fully inflated in order to reduce stress from wind resistance. Balloons may be suspended from land or from a floating object in the water. They should not be located near trees or other objects that could cause puncturing. Balloons should be tethered on 40-75 feet (12-23 m) of 48 lb (22 kg) or stronger monofilament line and initially spaced at least every 200 yards (183 m). Some balloons should be set very high to deter birds from flying overhead.

Advantages

- Inexpensive; and
- Readily available.

Disadvantages

- Rapid habituation;
- Ineffective at night;
- Do not function well in winds over 10 mph; and
- Potentially subject to ultraviolet degradation.

Flags

Flags are considered an effective and inexpensive hazing device for waterfowl. They can be constructed by mounting a three-by-two-foot (91-61 cm) sheet of black plastic to a four-foot (1.2 m) stake. The stakes

should be driven into the ground at an angle so the flags will move in light wind. They should be erected every 100 to 200 feet (30-61 m) on land, or on buoys over water. Mylar car dealership flags can also be effective for hazing waterfowl. Flags can be used in conjunction with gas-operated exploders.

Advantages
- Inexpensive; and
- Readily available.

Disadvantages
- Rapid habituation; and
- Ineffective at night.

Human Effigies and Predator Models

Human effigies (e.g., traditional scarecrows) and raptor models may be effective if they appear lifelike, have motion, are frequently repositioned, and are used in combination with loud sounds or recorded distress calls. Human effigies are more effective if you first establish the human form as being potentially detrimental (e.g., have response personnel create disturbance in the area before deploying human effigies), and are dressed similarly to personnel operating in the area.

Advantages
- Readily put in place;
- Easily remobilized;
- Does not constitute an auditory disturbance near populated areas or responders;
- Effective in good and bad (winds, rain, etc.) weather; and
- Relatively inexpensive (<$200).

Disadvantages
- Effectiveness limited to daylight, except if equipped with lights or combined with audio deterrents;
- Rapid habituation by birds (a few days); and
- Small range of effectiveness (100m or 4-8 ha).

Reflectors, Mirrors, and Reflecting Tape

Reflector devices can be constructed by attaching aluminum or tinfoil pie plates to a line suspended over land or water. These devices can be used in association with lights to haze waterfowl. Hand-held mirrors that reflect sunlight may also be effective. Mylar reflecting tape is another deterrent for many species of birds. This silver and red-coated tape is generally twisted and strung between support posts. The tape reflects sunlight, and vibrates under windy conditions producing a humming noise.

Advantages
- Inexpensive.

Disadvantages
- May attract, rather than deter, birds; and
- Ineffective at night.

Lights

Strobe, barricade, search, and revolving fixed lights have been used to haze birds, and they should be combined with other deterrent techniques such as exploders and pyrotechnics. Although lights may be partially effective for deterring waterfowl during the night, some bird species may be attracted to lights, especially during rain, fog, or heavy cloud cover.

Advantages

- Inexpensive.

Disadvantages

- May attract, rather than deter, birds.

Lure Areas and Bait Stations

Birds may be lured from one area to another with the use of bait food. However, bait stations require that large quantities of bait food be available over a period of days. Because lure areas need to be relatively close to a spill so that the food can be detected, this proximity may increase the oiling risk to birds attracted into the general area. Lure areas are recommended only when, after careful evaluation, alternative techniques would be expected to be ineffective.

Advantages

- Passive form of deterrence.

Disadvantages

- May attract birds not normally present in the area and increase potential for oiling as birds disperse from baited site.

Dyes

The feasibility of using dyes for deterring birds from oil spills is unknown because of data gaps including: species-specific reactions to colors, habituation potential, dye toxicity, dye solubility in various types of oil, concentration required, and rates of dye weathering. Therefore, use of dyes is NOT recommended as a bird deterrent during oil spill response at this time.

Trained Falcons and Hawks

Trained falcons and hawks are sometimes used at airports to chase away birds and disperse birds from runways. If used in a contaminated or oiled area, there is the potential that these trained birds could themselves become oiled or contaminated, or could potentially chase or disperse birds into contaminated areas. Using trained falcons and hawks is NOT recommended as a bird deterrent during oil spill response.

Decoys and Visual Devices

Dead-bird decoys or bird carcasses are sometimes used to discourage birds from using an area. However, placing dead-bird decoys or bird carcasses in a contaminated or oiled area may attract healthy birds of prey or other mammalian predators, potentially causing these predatory species to become contaminated or oiled. Using decoys and carcasses is NOT recommended as a bird deterrent during oil spill response.

Appendix 4. Bird Natural History and Special Concerns

Body Shape	Group (Order) Examples	Physical Characteristics Natural History	Bird Collection and Care - Special Concerns
	ALCIDS (Charadriiformes) Common Murre Rhinoceros Auklet Cassin's Auklet Pigeon Guillemot Tufted Puffin Marbled Murrelet Ancient Murrelet	Divers that use short narrow wings to fly underwater and use feet to steer, short legs attached toward the rear of the chunky body, have short-tail, large head, only three toes (all webbed) and dense waterproof plumage. Most prefer open sea, very gregarious, most nest in colonies on offshore islands. Nest disturbance can seriously reduce the success of a breeding season. Most molt all their flight feathers at once and are flightless for a period.	Some may be able to stand, but padding in box/ pen should be provided; those that stand on the entire foot up to the ankle are more awkward on land. Prone to foot and joint infections. Smaller alcids should be provided with hiding places. Can be aggressive, be careful of sharp beak. Birds will often be comforted by presence of others of their species in the same pen. Murres out on the water that have lost waterproofing will sometimes create a lot of splashing by flapping their wings while trying to stay afloat at the surface.
	**CORMORANTS & PELICANS** (Pelecaniformes) Brandt's Cormorant Double-crested Cormorant Pelagic Cormorant Brown Pelican	Foot propelled diving birds, have short legs to the rear of a stout body, long neck, with long beak sharply hooked at tip and no external nostril openings, long stiff tail, webbed foot (all 4 toes are webbed), are very aquatic and strong fliers. Feathers not completely waterproof. Gregarious, nest in colonies, can sink partly or completely below surface by squeezing air out of plumage. Swim low on the water. Can often be seen perching with wings held out.	Allow bird to breathe through its mouth. Always maintain head control, can strike and inflict severe bite. They walk poorly; can be provided rocks or slumps for perching in pen and padding in box/pen. It can help to support the strong feet when holding for tubing, etc. They may be more still and easier to work with this way.

Source: *Oiled Bird Search and Collection Training Course,* Marine Oil Spill Workforce Manual, BC Environment

Body Shape	Group (Order) Examples	Physical Characteristics Natural History	Bird Collection and Care - Special Concerns
	GREBES (Podicipediformes) Horned Grebe Eared Grebe Red-necked Grebe Western Grebe Clark's Grebe	Foot propelled diving birds with short wings, rudimentary tails, slender pointed bill, four lobed toes with partial webbing, legs far back on body, soft plumage, very aquatic, weak fliers. Rarely on land, even to breed.	Head needs to be controlled so that handler avoids being struck by sharp beak. Awkward on land, will feel safest in the water, not likely to come ashore until they have to. Prone to getting sores on keel, so need lots of padding in boxes and pens. Likely to become soiled in pens because they don't move away from their own droppings. Handlers should try to avoid projectile feces. May fight among themselves and peck at each other in crowded conditions. Prone to getting an impacted cloaca.
	LOONS (Gaviiformes) Pacific Loon Common Loon Red-throated Loon	Large, foot propelled diving birds, with legs far back on long body, straight sharp beak, hard compact plumage, wings narrow and pointed. Loons have four toes, (front three are webbed). Rarely on land, except to breed, on shore, of lakes and ponds. Extremely sensitive to human disturbance near nest. Migratory. Flightless period during fall molt. LEG POSITION OF WALKER (Pheasant) VS DIVER (Loon) 	Strong birds with sharp beaks; need to always control head, usually need two people to handle a loon. Wear goggles. Will feel safer in the water and less likely to come onshore (until they have to); awkward on land. Very susceptible to stresses of captivity. Prone to sores on keel so need lots of padding in boxes and pens. May fight among themselves and hurt each other in crowded conditions. Prone to getting impacted cloaca. Likely to become soiled because they don't move away from their own droppings. Light oiling on surface feathers may not penetrate enough to destroy waterproofing. Handlers should try to avoid projectile feces.

Source: *Oiled Bird Search and Collection Training Course,* Marine Oil Spill Workforce Manual, BC Environment

Body Shape	Group (Order) Examples	Physical Characteristics Natural History	Bird Collection and Care - Special Concerns
	SEA DUCKS & BAY DUCKS (Anseriformes) Canvasback Surf Scoter Black Scoter White-winged Scoter Bufflehead Goldeneye-Common, Barrows Harlequin Duck Scaups-Lesser Greater Oldsquaw	These sea ducks & bay ducks have relatively short legs and tails, most have broad flattened beaks, with dense plumage and the three front toes webbed, hind toe is lobed. Diving ducks are foot propelled with large, more widely spaced feet that make them less balanced on land than dabblers. Legs are short and farther to the rear of their bodies. Diving ducks have smaller more pointed wings than dabbling ducks. (Some diving ducks use both feet and wings when swimming underwater). Found in open ocean and bays. Most are migratory.	Diving ducks must build up air speed before taking off. Prone to sternal lesions, foot and joint damage, and should have padding in box/pen. Divers are less inclined to come ashore than dabblers (until they have to). A light oiling on the surface of dense plumage may not affect waterproofing. Most duck beaks are not dangerous to handlers. Male and female ducks generally have very different plumage; males are often aggressive toward females and sub adults, especially in crowded pens. Scoters will often go limp when being handled; this is not an indication that they are in serious trouble; they also can be aggressive, hissing and striking out, but there is little chance of them hurting handlers.
	STIFF-TAILED DUCKS (Anseriformes) Ruddy Duck	Stiff-tailed ducks have big feet and long tails, often held erect. Ruddy ducks' feet are so far back that they are nearly helpless on land. Ruddy ducks are the most aquatic diving ducks and can quietly sink below the surface without making a ripple Found in ponds, lakes & shallow bays.	Stiff-tailed ducks can be very shy; should be given hiding places. Ruddy ducks are nearly helpless on land and need padding in boxes and pens.

Source: *Oiled Bird Search and Collection Training Course,* Marine Oil Spill Workforce Manual, BC Environment

Body Shape	Group (Order) Examples	Physical Characteristics Natural History	Bird Collection and Care - Special Concerns
	DABBLING DUCKS (Anseriformes) Eurasian Wigeon Northern Shoveler American Wigeon Green-winged (Teal) Northern Pintail Gadwall Mallard	Dabbing ducks have short legs placed more to the front of the body, feet are generally smaller than those of diving ducks, have larger less pointed wings than the divers and dense plumage. Unlike seaducks, hind toe is not lobed or flattened. Usually feed in shallow fresh or salt water by tipping up the tail and reaching below the surface. Most rarely dive except to escape danger.	Dabbling ducks can bound directly from surface into flight; pens should be covered (i.e., netting), boxes should not be opened completely before handler is ready to hold duck. Easiest of the water bird groups to handle; more resistant to stresses of captivity. Males may be somewhat aggressive toward sub adults or females, especially in overcrowded pens. Light oiling on surface feathers may not penetrate enough to destroy waterproofing.
	GEESE (Anseriformes) Brant Snow Goose Canada Goose Whitefronted Goose	Geese have a large body, long neck, stout bill and dense plumage. Legs of geese are placed further forward on the body than on ducks and swans, which gives them better balance for walking. Swim and feed at water surface, often tipping up. Highly social. Have strong family bonds and lasting pair bonds.	Can be very aggressive, especially during breeding season (threatening displays are common). Powerful wings and legs, some have bony knob at carpet joint of wings that can inflict injury. It may be easier to hold the goose against the ground while its wings are controlled and then wrap a sheet around the wings and lower body, then it can be picked up and carried more easily. Can walk or run well. Because of dense plumage, light oiling on surface feathers may not penetrate enough to destroy waterproofing.

Source: *Oiled Bird Search and Collection Training Course,* Marine Oil Spill Workforce Manual, BC Environment

Body Shape	Group (Order) Examples	Physical Characteristics Natural History	Bird Collection and Care - Special Concerns
	SHOREBIRDS (Charadriiformes) Oystercatcher Turnstones Plovers Dunlins Sandpipers Phalaropes	Most are long-legged, and are seen walking, running or wading in or near the water. The larger shorebirds have long necks. Most have slender, specialized bills, They have dense plumage and are good fliers. Primarily wading shorebirds, often in large flocks. Most probe mud or sand. Can walk or run quickly.	Smaller shorebirds can benefit from being boxed or penned together. Many species are shy and should be provided hiding places in pens. Many species are small and delicate; require careful handling and are very susceptible to hypothermia. Oystercatchers' nest on offshore rocks and islets (on rocks and gravel) can be easily disturbed by people or boaters in their areas in spring. Many shorebirds prefer mud flats (areas where oil will persist).
	HERONS (Ciconiiformes) Great Blue Heron	Long necked, long legged waders with long, rounded broad wings, short tail, long bill and four long widely spread toes. Most are wading feeders. They are usually solitary except during breeding.	Long legs subject to trauma especially if cramped. Have sharp, pointed beaks and may aim for eyes of handlers--so always maintain head control. Wear goggles. Very shy and sensitive to human presence; provide visual barriers. Should be provided a perch and housed alone.
	TERNS (Charadriiformes) Common Tern Caspian Tern	Long narrow wings, dense waterproof plumage, long tail usually forked, sharp, pointed bill, no hook, webbed feet, short legs, but not strong swimmers on surface. Often hover and plunge head-first into water. Colonial breeders, migratory. Most terns mate for life. Long distance fliers.	Poor swimmers. Do not swim well on the water's surface. Have sharp cutting beaks.

Body Shape	Group (Order) Examples	Physical Characteristics Natural History	Bird Collection and Care - Special Concerns
	GULLS & JAEGERS (Charadriiformes) Glaucous-winged Gull California Gull Thayer's Gull Bonaparte's Gull Heermann's Gull Black-legged Kittiwake Mew Gull Herring Gull Ring-billed Gull Western Gull Parasitic and Pomarine Jaeger	Long pointed wings, dense waterproof plumage, short, fan-shaped tail, bill hooked at tip, webbed feet, agile walkers and runners, good swimmers on surface. Usually feed from surface. Gregarious. Colonial breeders. Migratory.	Can take off straight up from the ground or water's surface. Have sharp beaks. May regurgitate food if alarmed. Dense plumage, light oiling on surface may not penetrate enough to destroy waterproofing.
	TUBE-NOSED SWIMMERS (Procellariiformes) Northern Fulmar Black-footed Albatross Fork-tailed Storm-Petrel Leach's Storm-Petrel Sooty Shearwater Pink-footed & Short-tailed Shearwaters 	Tube-nosed swimmers have a hooked, deeply, grooved bill with nostrils enclosed in one or two tubes on the top of the bill. They have long narrow wings, webbed feet, and thick plumage. (Excess salt is excreted through tubular nostrils. Small pockets in the nasal passages may sense velocity of air currents.) Migratory, off-shore seabirds. Some, like the Black-footed Albatross and the Northern Fulmar, will follow and sometimes land near ships in search of food (and are attracted to fish oil thrown overboard). Most are colonial breeders. Usually come ashore only for breeding.	Shearwaters and Fulmars often rest weight on toes and lower legs giving them a somewhat crouching posture on land. May require padding in boxes and pens. Many medium and large size members of this group are capable of delivering hard bites. May regurgitate strong-smelling stomach oil when alarmed, and this may soil nearby birds. Live birds not usually found on shores unless they are sick or oiled. Shearwaters have strong feet and sharp nails which can inflict wounds.

Appendix 5. Euthanasia Guidelines

Rehabilitators must administer euthanasia in accordance with 50 CFR §21.31(e)(4)(iii). In addition, rehabilitators who treat migratory birds at oil and hazardous waste spills should do the following:

1. Euthanasia should be considered for a bird having serious injuries that will require extended treatment or render it unable to survive in the wild. Serious injuries can include fractured limbs (particularly those affecting a joint), injuries to the beak, extensive soft tissue injuries, and significant visual or auditory deficits.

2. When large numbers of birds are contaminated in a spill, it is necessary to selectively treat them so the appropriate attention is given to those with the greatest probability of survival. Packed cell volume (PCV), relative weight, and body temperature are used to identify those birds having reduced chances of survival.

   Birds having a PCV of less than 20 percent may require an extended period of treatment, and are thus at a greater risk of developing secondary complications. This is especially true for seabirds that may have little resistance to terrestrial disease organisms. Birds that are both underweight and hypothermic (relative to other birds of the same sex/species involved in the spill) have been shown to have a significantly decreased survival rate. A bird having consistently low body temperatures (less than 100º F.) despite attempts to warm the animal are considered a poor risk.

3. Birds showing signs of infectious disease should be isolated, and either supported until a diagnosis is made or euthanized and necropsied. Birds with lesions characteristic of avian pox (warty lesions around the eyes, mouth or on the feet) should be isolated and precautions taken to prevent exposure to other birds. Other signs which should arouse suspicion include: bloody or mucous discharge from the eyes, nose or mouth; moist or gurgling respiratory sounds; watery or bloody diarrhea; regurgitation; rapid weight loss; or pronounced neurologic signs.

4. Birds that show signs of chronic disease, such as extreme emaciation, have a very poor prognosis. Consider euthanasia for a very underweight bird that has wasted pectoral musculature and a prominent keel. However, note the following: the keel is normally very prominent in species such as herons and egrets; at certain times (the end of winter or migration), birds may also have reduced muscle mass with no underlying disease process; and severely dehydrated birds are often underweight but will gain rapidly with rehydration.

5. The degree of oiling, the temporary presence of bleeding from the GI tract, and molting are NOT considered adequate grounds for euthanasia.

6. Approval by Federal or State agencies is required before certain birds can be euthanized. This applies to threatened or endangered birds, migratory birds, unusual

birds with small local populations, and species with low reproductive potential. All birds that are euthanized must be disposed of as instructed by the Division of Law Enforcement or the USFWS on-scene oil spill coordinator, as the birds they possess may be essential evidence for a civil or criminal investigation conducted by the USFWS or other agencies.

7. Techniques for euthanasia:

   a. Appropriate for the size of the animal;

   b. Designed to minimize stress;

   c. Reliable and rapid.

   d. Safe for personnel administering technique.

8. Chemical injection as discussed below is recommended and preferred. Alternative techniques are mentioned but not discussed.

   a. Injection, according to dosage guidelines, of a commercial euthanasia solution, with prescribed routes usually being the medial metatarsal, right jugular or brachial veins, will quickly and painlessly kill most birds.

   b. Most euthanasia solutions are restricted drugs and subject to control by the Drug Enforcement Administration: professional supervision, inventory control, and locked storage are required. All solutions must be obtained through a veterinarian and used under veterinary supervision.

   c. Ensure that animals euthanized by this method do not become food for carrion eaters.

9. Alternative techniques of chemical euthanasia include inhalation of anesthesia or toxic gases. Physical euthanasia is not recommended.

10. Refrigerate all dead birds until necropsied. Post mortems conducted in-house can yield information that will help in determining treatment protocols in live birds at the facility. All carcass disposal should be coordinated with the Division of Law Enforcement or the USFWS on-scene oil spill coordinator and disposed of consistent with spill incident-specific instructions and chain-of-custody protocols.

Fish and Wildlife Protection Strategies

9738 Fish and Wildlife Protection Options

Primary Response

The primary response strategy for fish and wildlife protection emphasizes controlling the release and spread of spilled oil at the source to prevent or reduce contamination of potentially affected species, their habitats, and sensitive environments. Specific primary response options include: mechanical or physical means; chemical or biological treatment; in-situ burning; and natural recovery. Oiled carcass collection is also considered a primary response effort.

Mechanical or physical methods are used to control spills through containment and recovery. Containment booms are used to control the spread of oil to reduce the possibility of polluting shorelines and other resources, as well as to concentrate oil in thicker surface layers, making recovery easier. Boom can also be deployed to keep oil that has been stranded on the shoreline from floating to another location. Recovery of contained or stranded oil can occur using various equipment and means including skimming, scraping, absorption, etc. Physical response methods include but are not limited to:

- Booming
- Skimming
- Barrier/Berm
- Physical Herding
- Manual removal/Cleaning
- Mechanical removal
- Sorbents
- Vacuum
- Debris removal
- Vegetation removal
- Flushing
- In-situ burning

Chemical treatment employs the use of dispersing agents, also called dispersants, that contain surfactants, or compounds that act to break liquid substances such as oil into small droplets. In an oil spill, these droplets disperse into the water column, where they are subjected to natural process—such as wind, waves, and currents—that help to break them down further. Chemical dispersants should only be used when the associated impacts of dispersed oil are less harmful than non-dispersed oil. All wildlife in the dispersant target zone should be identified prior to approving the use of dispersants. Birds within the dispersant target zone should be hazed or captured if they become contaminated. Dispersants should not be applied over large concentrations of birds.

Others types of chemicals may also be employed to assist with recovery such as elasticity modifiers, emulsion treating agents, shoreline pre-treating agents, solidifiers, surface

collecting agents and surface washing agents. Like dispersants, all of these chemicals require RRT approval prior to use.

Biological treatment uses biological agents such as nutrients, enzymes, or microorganisms that increase the rate at which natural biodegradation occurs. Biodegradation of oil is a natural process that slowly removes oil from the environment.

In-situ burning of oil involves the ignition and controlled combustion of oil. It can be used when oil is spilled on a water body or on land. Use of this technique also requires RRT approval.

Natural recovery, leaving the oil alone, allows natural processes to remove the oil from the environment. Natural processes include evaporation, oxidation, and biodegradation. Natural recovery is not recommended for areas supporting wildlife concentrations.

Oiled carcass and debris retrieval operations are established in conjunction with primary response activities to remove short term sources of contamination and reduce food chain "contamination". Oiled carcasses, vegetation, and debris are collected and removed to prevent secondary oiling or additional contamination of wildlife as a result of predation and grazing. USFWS responders can assist with the collection of oiled wildlife and are responsible for cataloging and maintaining chain-of-custody for oiled migratory birds. In some cases, the USFWS may recommend that the FOSC seed the assistance of USDA 's Animal & Plant Health Inspection Service (APHIS) - Wildlife Services to help with carcass collection. USFWS Law Enforcement and/or a State Conservation Officer will supervise all morgue operations.

Secondary Response

Secondary response methods to protect fish and wildlife from an oil spill involve maneuvering healthy and uncontaminated fish and wildlife away from contaminated sites by use of deterrents, hazing, and preemptive capture.

Following an oil spill, it may be necessary to initiate a *deterrence or hazing* program that disperses and excludes unoiled or oiled / injured wildlife from contaminated areas to reduce mortality. If warranted, deterrence activities are initiated as soon as possible following an oil spill to prevent animals from establishing or continuing regular use patterns within a contaminated area. Deterrent devices used to disperse wildlife include both visual and auditory techniques, using both simple and sophisticated devices in order to respond to the unique habits of different species, surrounding environments, and the spill situations. Careful consideration should be given in the selection and placement of deterrence devices to prevent driving unoiled wildlife into oiled areas. In some cases, the USFWS may recommend that the FOSC seek the assistance of USDA APHIS Wildlife Services to help haze wildlife away from areas contaminated with oil and away from oiled wildlife / carcasses.

Fish deterrence techniques may include use of light, sound, smell, bubble curtains of air and herding nets to herd fish away from hazard areas.

Pre-emptive capture includes the capture, handling, transportation, short-term holding and release of healthy, uncontaminated wildlife. Prior to initiating a pre-emptive capture effort, it is essential to establish a release site or a holding facility and a release plan. Pre-emptive capture is recommended when there is a high potential for oiling sensitive wildlife species that are not easily hazed. However, this secondary response option has limited application based on species-specific criteria. The primary concerns when conducting pre-emptive capture are human and animal safety and minimizing transportation and holding times. Safety of the animal should focus on stress reduction as follows:

- Have equipment necessary to handle and transport animals as quickly and efficiently as possible;
- Minimize the number of vessels, aircraft, all-terrain vehicles, etc. to herd and capture animals in a given area;
- Avoid unnecessary noise and disturbance during capture efforts;
- Never pursue the animals to the point of exhaustion; and
- Minimize human contact with the animals except to provide veterinary care.

Nets, electrofishing and anesthetizing agents (e.g.,Tricaine Methanesulfonate) may be used to capture and remove fish to non-hazardous waters of similar temperature and chemistry.

Tertiary Response

Tertiary response is the capture and treatment or rehabilitation of wildlife contaminated by oil. It is implemented as the last resort for protecting wildlife. Oiled wildlife rehabilitation includes all elements related to capture, handling, transportation, stabilization, cleaning, care, holding, and release. The goal of a capture and treatment effort is the release of healthy wildlife back into their natural environment. The decision to initiate such an effort must consider incident-specific criteria. The criteria must be based on the best available science and focus on the protection and maintenance of healthy wild populations of the species affected by the spill. Considerations for initiating an oiled wildlife capture and treatment program include: condition of the animal, weather, oil toxicity, time, species of animal, extent of oiling, care in captivity, location of treatment, available care, facility, release, zoonotic diseases, permits and euthanasia.

There is no protocol available for capture, cleaning and treatment of oiled fish.

Annex GG

Oil Spill Annex

Oil Incident Annex

Oil Spill Incident Annex – Sector Delaware Bay

Introduction

A response to an actual or threatened release of oil is responded to under the National Contingency Plan (NCP). A response can vary greatly, involving only a few people or thousands. The initial action taken by responders sets the tone and direction of the response. Some very large incidents may also be responded to under the National Response Framework (NRF). [Link to Oil and Hazardous Materials Annex in the National Response Framework].

Purpose

The purpose of this Annex is to facilitate the rapid establishment of a multi-agency and responsible party incident command team to respond to an oil spill occurring in the coastal zone. ***This Annex should be used in conjunction with the ACP's Base Plan*** and if the cause of the incident is a suspected or actual terrorist incident, used in conjunction with the ACP's Terrorism Incident Annex.

The guidance in this Annex includes:

Unified Command Organization

The make-up of the Unified Command organization for a multi-agency oil spill response is usually comprised of representatives from the:

- US Coast Guard
- Pennsylvania Department of Environmental Protection
- New Jersey Department of Environmental Protection
- Delaware Department of Natural Resources and Environmental Control
- Responsible Party

However, the actual makeup of the Unified Command (UC) must be made on a case-by-case basis. Depending on the incident, additional federal, state, or local agencies may comprise the UC, as appropriate and necessary.

Note that PA, NJ, and DE state policy may require additional state agencies representing their interests in the UC if:

- Citizens have been harmed
- There is the possibility that citizens could be harmed

The state emergency management agencies (PEMA, NJ-OEM, DEMA) are to be notified of oil spills whenever the above conditions exist or if the spill is in excess of 1,000 gallons, for their information.

In general terms, an organization may be included in the UC if:

- The organization has jurisdictional authority or functional responsibility under law for oil spill response
- The organization is specifically charged with commanding, coordinating or managing a major aspect of the oil spill response
- The organization has resources to support the oil spill response
- The organization's area of responsibility is affected by the oil spill or the response operation

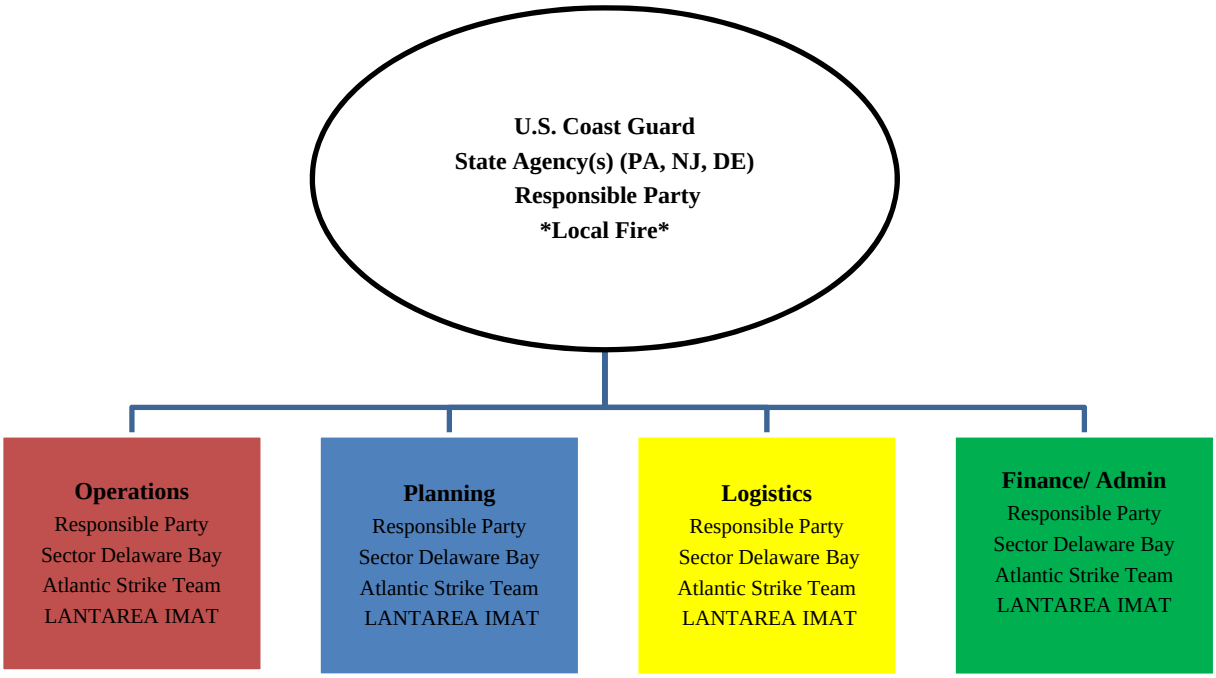

Figure 1 is a generic illustration of the agencies and/or entities that could serve in the Unified Command and General Staff. The list of agencies is not exclusive.
* Local Governments are encouraged to contact the Unified Command through the Liaison Officer.

Unified Command Objectives

Incident Commander References:

- [Link to U.S. Coast Guard, Incident Management Handbook (IMH), August 2006, Chapter 4 for examples of key decisions and objections]
- [Link to Incident Commander Job Aid]
- Various ICS Position Job Aids can be found on the Coast Guard's HomePort website (HomePort> Library> Incident Command System ICS>)
- The U.S. Coast Guard's Contingency Preparedness System which is a repository of lessons learned from exercises and real world events.
- MOU between the USCG, EPA & Corporation for National and Community Service TBD

The Incident Commander(s) / Unified Command (UC) set the tone for the response by developing response direction and guidance for the Incident Management Team (Response Organization). Chapter 4 of the U.S. Coast Guard, Incident Management Handbook (IMH) provides a list of decisions, incident priorities, incident objectives, and common tasks typically utilized during a spill. A link to the IMH is provided immediately above.

Considerations and Actions of the Coast Guard Incident Commander (CGIC)/Unified Command:

- Utilize the Oil Pollution Quick Response Card (QRC) [Link to Oil Pollution QRC]

- Make a determination if it is Safe to Respond [Link to Safe to Respond Policy]

- Follow Endangered Species Act requirements [Link to ESA Emergency Response Section 9717]
    - Notify the Regional Response Team representatives of the Department of Interior and Department of Commerce (NOAA) regardless of whether listed species or critical habitat are impacted
    - Determine if federally listed Threatened and Endangered species or critical habitat are present or could be present. If they are present, initiate Endangered Species Act informal Section 7 consultation with the United States Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS) [Link to Federally Listed Threatened and Endangered Species location information], [Link to example Informal Consultation Section 9735], [Link to ESA MOA Signed Copy Sec. 9716],
    - Document any written or oral communications that involve decisions on endangered species or critical habitat
    - Notify the USFWS and NMFS representative on the Incident Command team of any response situation changes that may impact endangered species or designated critical habitats
    - Ensure that response strategies and tactics are planned to minimize impacts to threatened or endangered species and designated critical habitats
    - Consult with state ICs regarding the presence of state listed threatened and endangered species and/or critical habitats in the; spill area, potential impact areas, and clean-up locations
    - **Post response: Complete consultation pursuant to the Endangered Species Act as is appropriate.** [Link to ESA Post-Response Section 9719]

- Determine if historic properties will be potentially impacted by response activities. Helpful information can be found at:
    - National Register of Historic Places (by state and county) see: http://www.nationalregisterofhistoricplaces.com
    - State Historic Preservation Office (SHPO) contacts see: http://www.ncshpo.org/find/index.htm#p
    - For information on the Programmatic Agreement on Protection of Historic Properties During Emergency Response Under the National Oil and Hazardous Substance Contingency Plan, see: http://www.achp.gov/NCP-PA.html
    - Refer to the guidance in Section 9711, Protection of Historic Properties: Oil Discharge and Hazardous Materials Release Emergency Response Phase Checklist [Link to Guidance Section 9711]

- Note that, before federal projects affecting historic properties can proceed, the National Historic Preservation Act (NHPA) requires all federal agencies to identify, preserve and manage eligible historic properties under their ownership or control. Section 106 of the National Historic Preservation Act (NHPA) requires "consultation" with the SHPOs and when agreement cannot be reached, with the Advisory Council on Historic Preservation (ACHP). See http://www.achp.gov/docs/OFAP_Org_Chart.pdf
- For ACHP Questions and Answers – Consideration and Treatment of Historic Properties During the Response to DEEPWATER HORIZON Oil Spill, see: http://www.achp.gov/docs/OilQandA.pdf
- If historic properties are present or could be present, contact the appropriate SHPO. Consult with SHPOs in the event that oil impacts structures that are 50 years old or more and the cleanup activities include:
  - Removing structures
  - Power washing structures
  - Ground disturbance
- Document any written or oral communications that involve decisions on historic properties

- Determine viability of employing countermeasures
  - Utilize the Selection Guide for Oil Spill Response Countermeasures http://epasg.genwest.com/index.html#
  - Dispersants [Link to dispersant protocols for the Delaware River Region Section 9720]
  - In-situ burning [Link to In-situ Burn Protocols Section 9718]
  - Additional information may be found on the Regional Response Team III website: http://www.rrt3-rcp.nrt.org/production/NRT/RRT3-RCP.nsf/AllPages/HomePage.html
  - The EPA's Product Schedule can be found at: http://www.epa.gov/oem/content/ncp/product_schedule.htm

- Ensure that the natural resource trustees are promptly notified of the incident and that the trustee-appointed Federal Lead Administrative Trustee or Lead Administrative Trustee coordinates NRDA activities, including any requests for assistance, with the Liaison Officer

- In the event that a Responsible Party decides to no longer fund a response action, consult the guidance outlined in the Transitioning from a Responsible Party Managed Response to a Federal Response [Link to Transition Document Section 9721]

- In the event that there is NO known responsible party, consult the guidance outlined in the Federally Managed Spill Response document. [Link to Federally Managed Spill Response document Section 9799]

- Establish a 3rd party claims process. The UC should consider/require the cleaning of recreational boats to be part of the response cleanup activities and not necessarily part of the claims process

Utilizing Command Staff Officers

The specialized staff positions that could be utilized during a spill are typically a Safety Officer; Liaison Officer; Public Information Officer; and the Intelligence and Investigations Officers. Additional positions may be staffed as necessary, e.g. Volunteer Officer.

The UC and personnel assigned to fill the Staff Officer positions should utilize the following for more information:

- [Link to U.S. Coast Guard, Incident Management Handbook]
- [Link to Public Information Job Aid]
- [Link to Joint Information Center Manual]
- [Link to Liaison Officer Job Aid]
- [Link to Liaison Manual]
- [Link to Safety Officer Job Aid]
- National Strike Force, Public Information Assist Team
- Coast Guard District 5 Public Affairs Detachment
- The U.S. Coast Guard's Contingency Preparedness System

Recommended "best practices" for selected Staff Officers include but are not limited to:

- Liaison Officer:
  - Identify the need for Assistant Liaison Officers to work with the States of DE, NJ, and PA. Assistants should come from the States.
  - Assist the Federal Lead Administrative Trustee, if assistance is requested, as Trustees conduct Natural Resource Damage Assessment and Restoration activities
  - Coordinate VIP visits
  - Coordinate local, state, and federal political visits

- Information Officer
  - Set up the Joint Information Center (JIC)
  - Begin social media monitoring
    - Television, websites and blogs
  - Identify needs and request NSF Public Information Assist Team and USCG District 5 Public Affairs Detachment as necessary

- Safety Officer
  - Have sufficient Assistant Safety Officers in the field to ensure compliance with Site Safety Plans and OSHA requirements
  - Requested advisory capacity assistance from OSHA

Operations Section Organization

The Operations Section will be organized to meet the needs of the incident. For large and/or complex oil spill response operations the Operations Section Chief may organize as shown in Figure 2.

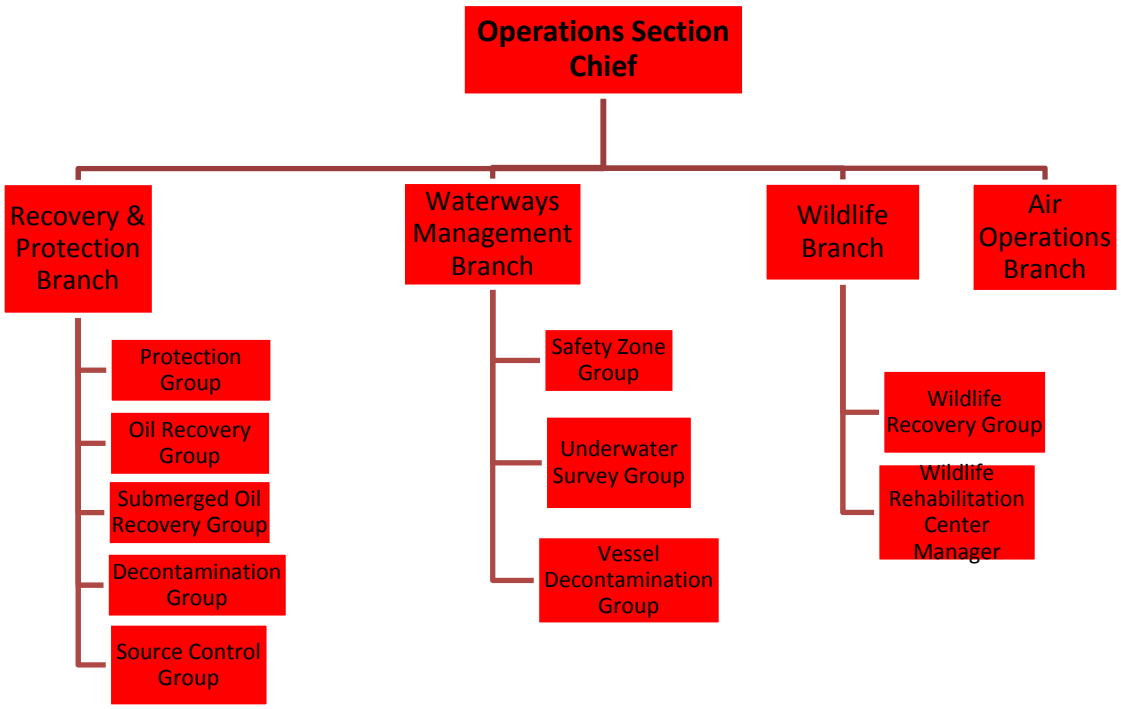

Figure 2. The size and makeup of the Operations Section is dependent on the size and complexity of the incident. For a major oil spill the Operations Section may be organized as shown above.

Operations Section Chief

The Operations Section Chief is responsible for the management of all tactical operations directly applicable to the primary mission.

Operations Section Chief References:

- U.S. Coast Guard, Incident Management Handbook, August 2006
- Operations Section Chief Job Aid
- Various ICS Job Aids for positions normally found in the Operations Section can be found on the Coast Guard's HomePort website (HomePort> Library> Incident Command System ICS>)

- See "Special Teams" at the end of this Annex. [Link to Special Teams]
- The U.S. Coast Guard's Contingency Preparedness System which is a repository of lessons learned from exercises and real world events.
- Pollution Removal Funding Authorizations (PRFA) for:
    - [Link to US Army Corps of Engineers PRFA]
    - [Link to State Environmental Agency PRFA]
    - [Link to US Fish and Wildlife Service PRFA]
    - [Link to Department of the Interior's Office of Environmental Policy & Compliance PRFA]

Responsibilities: The Operations Section Chief should also refer to the Oil Spill Quick Response Card utilized by the initial IC to confirm actions and notification that were taken. Depending on the complexity of the spill, a Multi Division/Group Organization or a Multi Branch Organization will need to be established (See: "Oil Spill" Chapter in the U.S. Coast Guard IMH). Overall, the Operations Section Chief is responsible for:

- Overseeing the initial assessment:
    - Determine or confirm location and time of spill; product and amount spilled; and area of known impact
    - Determine immediate safety hazards
    - Obtain best estimate of oil movement for next 12 hours based on current weather and tides
    - Identify areas that will be impacted

- Implementing protective booming strategy [Link to Strategies]
    - Prioritize protective booming (The Area Committee has determined that protecting openings to wetlands is the number one priority for protective booming. The philosophy is that oil can be deflected onto any river bank but must be prevented from going up tributaries into the wetlands.)

- Initiating efforts to control the source
    - Ensure actions are being taken to control and secure the source
    - If necessary, recommend establishing a safety zone
    - Contain the spill

- Establishing response branches (Recovery and Protection, Emergency Response, Air Operations, Waterways Management, Wildlife), as needed

- Consider conducting pre-impact cleanup of shoreline

- Identifying staging areas to be used [Link to pre-identified staging areas]

- As directed, conducting dispersant operations [Link to dispersant protocols Section 9720]

- As directed, conducting In-situ Burn operations [Link to In-situ Burn Protocols Section 9718]

Recovery and Protection Branch

The Recovery and Protection Branch is responsible for overseeing and implementing the protection, containment and cleanup activities as established in the IAP.

Protection Group

- Utilize Oil Spill Response Tools (See Electronic ACP's "MAPS" Section)
    - Based on location of spill, amount released, weather and other factors determine what areas will be impacted and the time they will be impacted
    - Provide prioritized protective booming list to the Operations Section Chief or Branch Director, if established

- Determine the organizations responding from or on behalf of the Responsible Party

- Is the local spill cooperative (Delaware Bay River Cooperative (DBRC)) responding?
    - If yes, confirm which boom sites have been ordered deployed?

- If the local cooperative is not responding, what organization(s) will be doing the protective booming? Note that the DBRC's response equipment is only available to co-op members unless the Coast Guard hires DBRC
    - Confirm which boom sites have been ordered deployed
    - Where will resources, materials and personnel come from?
    - Are the personnel familiar with the booming plans?
    - What is the time frame for accomplishment?

- Provide information to Waterways Management in order to issue a Notice to Mariners for protective boom sites. Ensure that the most up-to-date information is provided so that adjustments can be made to the broadcast(s)

- Ensure that the Incident Action Plan includes any necessary special instructions that deployed booms are to be lighted and/or attended

- Monitor and maintain the activities at boom sites and report back daily to Operations with observations.

- Based on overflight information:
    - Determine additional sites that will have to be boomed and establish priorities
    - Identify other potential sites (other than openings to wetlands) that may require protective booming

- Identify additional staging areas to mobilize
- Identify resources to be mobilized (equipment and personnel)
- Repeat above until no further protective booming is needed

- Determine protective boom sites to be removed, decontaminated, or disposed of, if necessary

Oil Recovery Group

General responsibilities include the need to:

- Advise the Operations Section Chief of the amount of oil that can be recovered based upon the amount of oil on the surface of the water; offshore, near shore and on the riverbanks and shorelines. Based on experience, suggest the types of resources that can be used.

- Obtain dedicated helicopter for on water recovery operations (the efficiency of the on water recovery will be severely impacted without air support)

- Establish communications with helicopter and/or on-water resources

- Obtain latest spill information to verify that the on-water resources are the best location to recover oil

- Provide feedback to the Operations Section Chief on the ongoing adequacy of the resources deployed

- Look at methods to enhance the recovery operations
  - Review the planned collection booming schemes in the ACP's Environmental Sensitivity Maps or ASAMAP data layer
  - Consider the possibility of using V-booms to enhance the encounter rates

- Determine the temporary storage required for the spill and the type required:
  - In the upriver area, Delaware City and above, land facilities, vacuum trucks, and/or barges may all be viable solutions for temporary storage to offload OSRVs
  - Below Delaware City, the temporary storage will be limited to barges to which OSRVs can transfer recovered oil

- Monitor the location of on-water resources and, if direct air support is not available, provide the OSRVs with the latest observations from any sources. Review the latest trajectory information to assist in keeping the OSRVs in areas where there is recoverable oil

- Consider the use of a vessel identification system (Automated Identification Systems (AIS)) to track the location of oil spill recovery vessels or vessels of opportunity

USCG District 5's District Response Advisory Team (DRAT) may be able to provide an Equipment Specialist/On Water Group Supervisor. Request the DRAT resources through the District 5 Command Center.

Submerged Oil Group (established when submerged oil is determined to exist)

- Develop a Submerged Oil Assessment Plan [Link to attachment 9756 Submerged Oil Assessment Plan for the ATHOS I Oil Spill]

- Locate and quantify recoverable submerged oil with remote sensing and or divers certified to dive in contaminated waters. Explore remote sensing options with NOAA and the USCG Research and Development Center. The local cooperative, DBRC, has some capability to detect submerged oil.

- Develop appropriate site safety plan

- Identify required resources based on quantity, viscosity, water depth and temperature

- For large quantities of submerged oil consider:
    - Platform (vessel, barge, etc.)
    - Contaminated water divers
    - Pumping equipment
    - Oil/water separation or decanting (Ensure actions are approved by the UC and permits are received prior to implementation)
    - Temporary storage
    - Transfer equipment
    - Disposal needs

- Small quantities of submerged oil:
    - Weighted snare or VSORS (Vessel Submerged Oil Recovery System)
    - Diver assisted recovery with viscous oil pom poms

Decontamination Group

- Identify types and amounts of equipment to be decontaminated
    - Large vessels (ships and barges) on water
    - Small vessels (See "Considerations and Actions of the CGIC/UC" to verify how cleaning of recreational vessels will be handled)
    - Oil Containment boom (Working with interested parties, determine if it is more cost effective to dispose of contaminated boom)
    - Skimmers

- Identify and locate suitable facility for decontamination activities
    - Suitably sized area for decontamination operation
    - Suitable area for staging equipment prior to and post decon
    - Consider location based on public use and access, preferably in a industrial area
- Work with the Safety Officer to develop an appropriate site safety plan considering approved cleaning agents (include information on the Material Safety Data Sheet)

- Identify and locate required resources
    - Decontamination pools
    - Pressure washers
    - Pumps
    - Water source
    - Wash water temporary storage
    - Wash water transport to disposal facility in accordance with waste disposal plan
    - Equipment handling (fork lift, crane)

- Develop appropriate tracking and documentation of equipment as it enters and departs decontamination facility

Source Control Group

The Source Control Group Supervisor is responsible for coordinating and directing all source control activities related to the incident. The Source Control Group can also be organized as the Salvage/Source Control Group, if necessary. Source Control activities include but are not limited to:

- Coordinating the development of the Source Control Plan

- Determining Source Control resource needs

- Directing and coordinating implementation of the Source Control Plan

- Managing the dedicated Source Control resources

Waterways Management Branch (WMB) The WMB within the Operations Section works closely with the Marine Transportation System Recovery Unit (MTSRU) within the Planning Section. The WMB actively ensures the safe movement of vessels within the established safety zone and the prioritized commercial facilities and vessels are decontaminated as quickly as possible to limit the impact to the port. All WMB activities and decisions should be briefed back to the MTSRU.

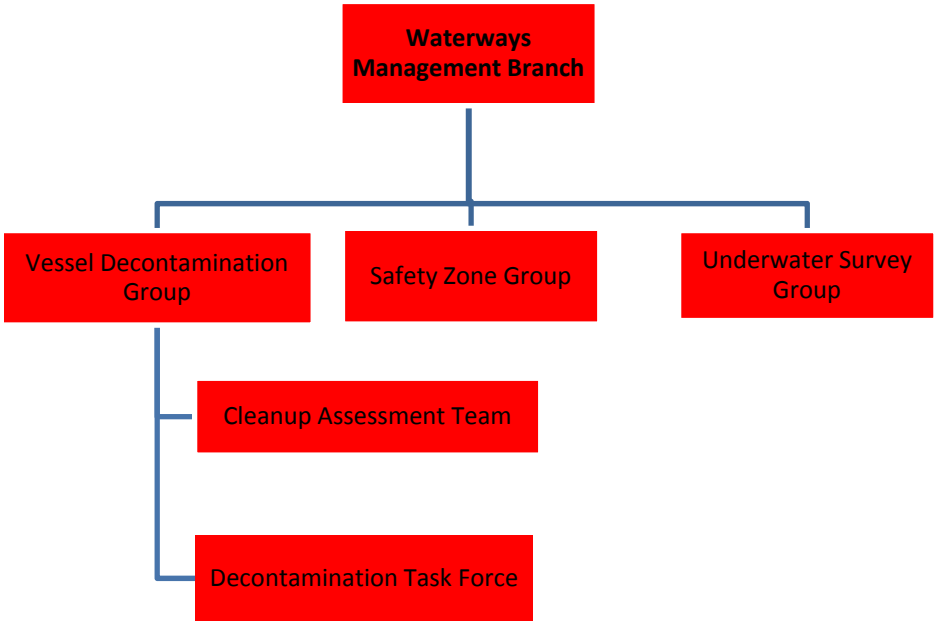

Figure 3. The Waterways Management Branch organization oversees the safe movement of vessels within the established safety zone.

Vessel Decontamination Group. The Supervisor oversees the implementation of the facility and vessel decontamination plan. Duties include:

- Utilize the daily decontamination priority list (received from the MTSRU) to coordinate decontamination priorities
- Assign and coordinate decontamination work assignments
- Ensure that safety briefings are conducted prior to each shift
- Ensure that decontamination schedule is communicated daily to the impacted Stakeholders

Cleanup Assessment Teams. Assessment Teams conduct assessments of facilities and vessels within the spill area to determine extent of oil contamination and if decontamination efforts meet established criteria for cleanliness. Activities and actions include:

- Receive daily work assignment from the Decontamination Group
- Document (written and photographic) findings for each facility and vessel assessed

- [Assessment Form Section 9728]
- [Sketch Map Section 9729]

- Check integrity of deployed boom around facility piers. Notify Decontamination Group Supervisor if boom is not performing as required

- Check vessels within the safety zone for oiling. Notify Decontamination Group Supervisor of vessel(s) status (contaminated or not contaminated)

Decontamination Task Force. Provide personnel and equipment to conduct commercial facility and vessel decontamination.

- Receive daily tasking and safety brief from the Decontamination Group Supervisor

- Clean facilities and vessels in accordance with the Vessel Decontamination Plan [Link to an sample Vessel Decontamination Plan Section 9736]

- Upon completion of decontamination efforts, coordinate with the Decontamination Group Supervisor to have the Cleanup Assessment Team inspect the vessel and verify that the decontamination meets established guidelines for cleanliness

Underwater Survey Group. The Survey Group is to conduct bottom survey activities within the established safety zone(s) to assure the overall safety of on-water activities. Activities include:

- Coordinate all diving and survey operations within the established safety zone

- Approve/disapprove dive safety plans

- Coordinate all dive and survey operations with the Vessel Traffic Management Group, Safety Zone Group and the Oil Recovery Group

Safety Zone Group. Utilize waterborne resources to enforce integrity of the safety zone.

- Enforce requirements of the safety zone

- Coordinate with the Vessel Traffic Management Group and the Decontamination Group to monitor and enforce all movement of vessels (commercial cleanup) that are arriving, departing or shifting berths within the safety zone

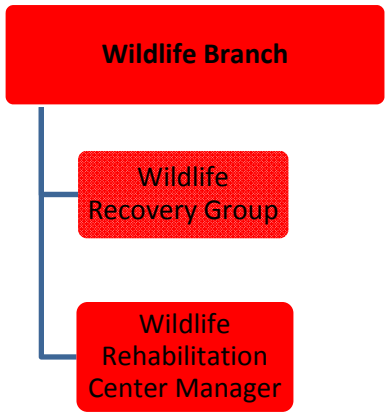

Figure 4. The Wildlife Branch within the Operations Sections is charged with actually conducting "field operations".

Wildlife Branch. When oiled wildlife is present or there is a possibility that wildlife will become impacted, the Operations Section Chief should standup the Wildlife Branch. This Branch deals with all operational wildlife issues, such as actually conducting; wildlife field assessments and surveys, deterrence, recovery, and rehabilitation of the impacted animals. The Wildlife Branch within the Operations Section works closely with the Environmental Unit and specifically the Wildlife Team within the Planning Section. The interaction between these groups helps to determine the best course of action for the response.

During a response, one or more of the following positions may be activated. In addition to the assigned tasks, each activated group is responsible for providing daily activity reports. Helpful references: Best Practices for Migratory Bird Care during Oil Spill Response (USFWS); Best Practices for Marine Mammals (NOAA).

- **Wildlife Branch Director**: The Wildlife Branch Director oversees efforts to minimize wildlife impacts during the emergency response including, but not limited to:
    - Coordinates teams for:
        - Field assessment and surveys
        - Live animal capture and carcass collection.
    - Establishes a facility for wildlife rehabilitation as appropriate
    - Consults on wildlife protection strategies
    - May provide input on potential impacts of response protection strategies on wildlife
    - Knowledgeable of all aspects of a wildlife response.
    - Responsible for ensuring that plans are executed and for day to day operations.
    - Ensures overall safety of the wildlife efforts
    - Ensures storage or disposal as appropriate is arranged for oiled carcasses

- Ensures wildlife responders possess appropriate state and federal permits for wildlife response activities

- **Wildlife Recovery Group**: This group coordinates the priorities and daily activities of all units with field assignments and is responsible to ensure that all assigned personnel adhere to safe work practices. The group follows the response organization's agreed upon procedures to order necessary equipment and supplies. This group may also be further divided according to impacted species (birds, marine mammals, sea turtles) with each unit below ramped up for species type.

    - Wildlife Assessment Unit
        - Collects accurate field data (number and location of oiled and non-impacted wildlife)
        - May be done via land, water and air resources

    - Hazing Unit
        - Executes the deterrence plan
        - Ensures deterrents are not displacing clean animals into oiled areas

    - Recovery Unit
        - Collects impacted wildlife (by land or water)
            - Live wildlife and carcasses
        - Utilizes trained personnel experienced in the capture of oiled wildlife
        - Follows transportation and stabilization guidelines
        - Ensures accurate records and chain of custody
        - Timely communication with Wildlife Rehabilitation Group

    - Wildlife Morgue Unit
        - Often staffed by agency law enforcement personnel
        - Ensures accurate records and chain of custody
        - Ensures appropriate storage of carcasses
        - May be co-located with rehabilitation facility when appropriate
        - References : Best Practices for Migratory Bird Care during Oil Spill Response (USFWS); Best Practices for Marine Mammals (NOAA)

- **Wildlife Rehabilitation Group**: This group coordinates the safe work practices of the day to day activities of the wildlife rehabilitation facilities and is responsible for the site safety plans of each facility. It is essential that this group utilizes trained personnel experienced in the rehabilitation of oiled wildlife. Responsibilities include but are not limited to:

    - Ensure accurate records and timely reporting to the Situation Unit and Joint Information Center (JIC)
    - This group may be divided according to species impacted (birds, marine mammals, sea turtles) with dedicated facilities for each
    - Identifies the need for and establishes stabilization sites as appropriate

- Secures equipment, supplies and specialized wildlife rehabilitation items as per the response organization's agreed upon procedures
- Maintain a status database of all wildlife (living or deceased) passing through the facility
- Ensures stabilization and rehabilitation protocols adhere to published guidelines accepted by federal and state natural resource managers.
  - References : Best Practices for Migratory Bird Care during Oil Spill Response (USFWS); Best Practices for Marine Mammals (NOAA)

Air Operations Branch. There is no specific number of aviation assets that will trigger when the Air Operations Branch is established. In order to schedule the aircraft best suited for the missions, the Air Operations Branch Director (AOBD) should discuss overflight mission objectives with the Operations Section Chief (and with the Liaison Officer, if necessary). Overflight missions may include:

- Mapping the distribution and appearance of the oil
- Verifying modeled forecasts of the oil movement
- Providing responders with an overview of the incident
- Directing cleanup operations
- Providing equipment/personnel
- Wildlife Surveys
- Monitor and document integrity and effectiveness of deployed booming
- VIP observers (e.g. Agency Administrators, Governors, etc)

Aerial Observation Considerations:

- In the early morning or early evening there is often not enough contrast to see some oils clearly
- The flight track should be set up to minimize the glare with the optimum schedule for mapping oil distribution depending on the angle of the sun in mid-latitudes. The middle of the morning or afternoon is usually a good viewing time. Personnel selected to conduct observations of oil spills should consult the Guidance for Aerial Observation of an Oil Spill [Link to Guidance for Aerial Observation of an Oil Spill Section 9740]

Planning Section Organization

The Planning Section is responsible for the collection, evaluation, dissemination and use of incident information and maintaining the status of assigned resources. In addition to the traditional ICS Planning Section Units, response to an oil spill may require additional units be added (Figure 4) to enable the Planning Section to support incident operations.

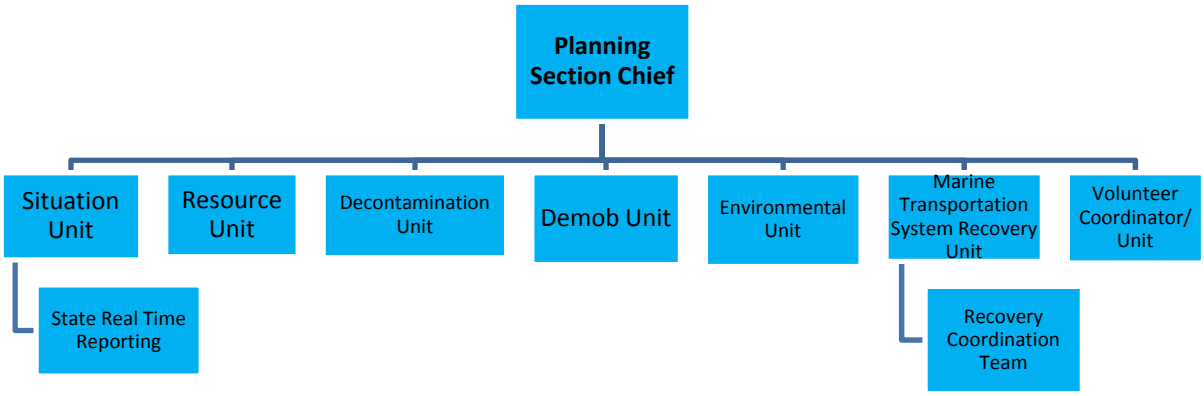

Figure 4. The Planning Section may require additional units not normally associated with the traditional ICS organization to enable the Planning Section to support response operations.

Planning Section Chief:

Depending on the size and complexity of the oil spill response, the Planning Section Chief should determine the need to establish various Units, such as the ones mentioned below, or to establish additional Units such as a Geographic Information System (GIS) Unit. In addition, the Planning Section Chief needs to determine the need to develop other supporting plans such as:

- Tarball and Debris Plan [Link to Tarball Plan Section 9744]
- Commercial Vessel Decontamination Plan
- Waste Disposal Plan
- Wildlife Recovery Plan
- Water Column Monitoring Plan
- Dispersant Plan
- In-situ Burn Plan

USCG District 5's District Response Advisory Team (DRAT) may be able to provide expertise and technical assistance to the FOSC during oil spills. Request the DRAT resources through the District 5 Command Center.

Planning Section Chief References:

- [Link to U.S. Coast Guard, Incident Management Handbook, August 2006]
- [Link to Planning Section Chief Job Aid]
- Various ICS Job Aids for positions or "tools" normally found in or used by the Planning Section can be found on the Coast Guard's HomePort website (HomePort> Library> Incident Command System ICS>)
- See "Special Teams" at the end of this Annex
- The U.S. Coast Guard's Contingency Preparedness System which is a repository of lessons learned from exercises and real world events.

Situation Unit

The Situation Unit is responsible for gathering incident information and ensuring that the information is 'pushed out' and shared throughout the entire command team. Helpful information can be found in:

- [Link to Section 4100 of the ACP]
- [Link to USCG Incident Management Handbook]
- [Link to Situation Unit Leader Job Aid]

State Utilization of "Real Time" Reporting Systems

Should the states of PA, NJ or DE, and their corresponding counties or municipalities utilize a web based, "real time" reporting system, such as Knowledge Center, eTeam, Incident Master, or Web-EOC to report oil sightings or impacted wildlife; the states are to supply the response organization with access to the systems and state specialists to enter data into the systems. These steps are to ensure smooth information flow "up and down" the reporting systems and between the response organization and the states of PA, NJ, and DE.

Prior to utilizing any state real time reporting system during the response, state Incident Commanders are to ensure that officials and representatives from their respective states know the Unified Command's agreed upon reporting procedures.

Resource Unit

The Resource Unit Leader (RESL) is responsible for maintaining the check-in, and tracking the current status (assigned, available, out of service) and location of all resources at an incident. Helpful information can be found in:

- [Link to Section 4200 of the ACP]
- [Link to USCG Incident Management Handbook]
- [Link to Resource Unit Leader Job Aid]

- [Link to Resource Tracking Flowchart – Resources from Other Federal, State or Local Governments]
- [Link to Resource Tracking Flowchart – Resources from Contractor]

Documentation Unit

The DOCL is responsible for the maintenance of accurate, up-to-date files. Helpful information can be found in:

- [Link to Section 4400 of the ACP]
- [Link to USCG Incident Management Handbook page]

For assistance in standing up the Documentation Unit, contact; Chuck Anglin, Response Documentation Specialist, TRACEN Yorktown, (757) 856-2920 Office, (757) 561-9275 Cell.

To ensure that UC decisions are formally documented, consider assigning a "Recorder" to the Unified Command.

Demobilization Unit

[Link to Section 4500 of the ACP]

Environmental Unit

[Link to Environmental Unit Leader Job Aid]
[Link with USCG Incident Management Handbook page 8-9]

The Environmental Unit responds to the changing demands of oil spills by developing with stakeholders a number of teams that execute specific tasks. The organization chart in Figure 6 includes several of the most common teams that work under the Environmental Unit during an oil spill response.

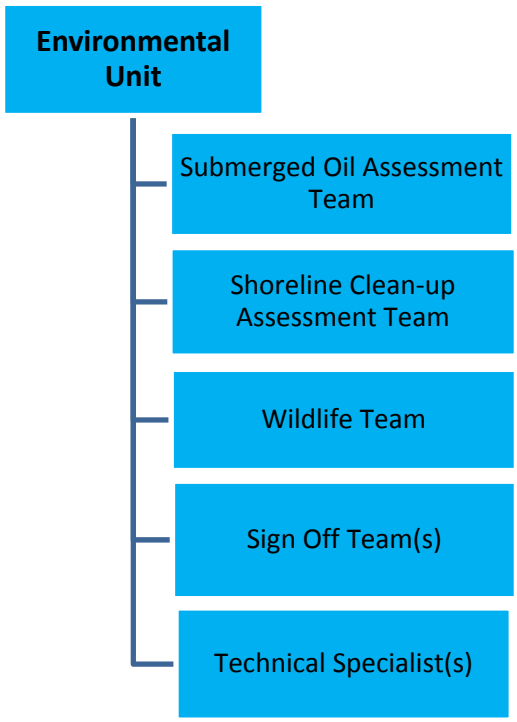

Figure 5. The Environmental Unit oversees a wide range of technical disciplines.

Environmental Unit Leader Responsibilities (not all inclusive)

- Assess the chemistry of the spilled oil to determine the oil's fate and effect in the environment

- Provide support to the Safety Officer in development of the Site Safety Plan

- Provide expertise on living marine resources and their habitats and information on associated cleanup and mitigation methods
    - Coordinate with Federal and State Resource Agencies and Trustees on the collection and dissemination of information on the environmental resources at risk, including marine resources

- Develop strategies to minimize environmental impact of the spill based on stakeholder consensus
    - Participate with State responders in the development of priority protection areas based on sensitive habitats [Link to Sensitive Area Maps]
    - Coordinate consultation with the State Historic Preservation Officers concerning the location of cultural and historic resources

- Develop environmental monitoring strategies that will help decision-makers understand the impact of response countermeasures that have been implemented

- Provide technical support to the FOSC during negotiations with representatives from the oil industry, the Port, the Nuclear Power Plant, and the Nuclear Regulatory Commission

- Provide information on meteorological, hydrological, ice, and oceanographic conditions
    - Provide technical report on future ice conditions
    - Provide technical report forecasting movement of the spilled oil

- Assemble and coordinate environmental stakeholders to reach consensus on protection priorities and cleanup strategies and endpoints
    - Consider establishing a Science Team that includes State representation and technical specialists to evaluate the technical issues and reach consensus
    - Through the Science Team, coordinate with stakeholders the development of endpoints [Link to sample End-points Section 9737] [Link to Delaware Estuary Science Directory]

- Work with Trustee agencies to begin the process of the Endangered Species Act Section 7 consultation [Link to example Informal Consultation Section 9735]

- Provide timely and complete status reports to the Planning Section Chief
    - Prepare environmental data for the Situation Unit
    - Provide weather, shoreline oiling, mapping and graphics for use in all briefings and situational updates, media briefings and public outreach forums

- As directed by the Unified Command, participate in news conferences, media availabilities, open houses and town hall meetings

- Establish and maintain the Response Link website for internal communications with response agencies

- Act as the liaison between the Unified Command and the Regional Response Team (RRT) providing the RRT with daily updates

- Coordinate requests from the Unified Command to conduct testing of alternative response strategies with the RRT

- Coordinate requests from vendors to evaluate a product's appropriateness for use during an incident using the Alternative Response Tool Evaluation System (ARTES). The process can be accessed through:
    - NOAA's website
    - Regional Response Team III's website

- Coordinate the activities of wildlife agencies and development of a Wildlife Recovery Plan

- Coordinate and support Unified Command requests for conducting hydrographic surveys

Submerged Oil Assessment Team

- Supports Submerged Oil Group activities

- Design submerged oil assessment strategies

- Ensure sample techniques are approved by the State(s)

- Coordinate placement of water column monitoring devices with the State(s)

- Provide leadership in the development of monitoring strategies for submerged oil [Link to example Submerged Oil Report Section 9756]

- Compile data reports

- Assess recovery techniques

- Identify potential impacts of oil and recovery techniques

Shoreline Cleanup Assessment Team (SCAT)

Shoreline Cleanup Assessment Team(s) are critical to supporting response operations by visually assessing impacted areas and determining the best methods of removal, enabling the Operations Section Chief to focus their response resources and refine their tactical plans [Link to NOAA Shoreline Assessment Manual]. The SCAT Team Leader responsibilities include:

- Determining the number of SCAT teams required

- Configuring the teams with members possessing proper training and skill sets to ensure appropriate stakeholder representation. At a minimum the team make-up should include:
    - Coast Guard Representative
    - Impacted State Representative
    - Responsible Party Representative
    - Land Management Agencies

  .

  All members of the SCAT shall have completed the NOAA SCAT course or an alternately accepted course. All members of the SCAT shall have the Hazardous Waste Operations and Emergency Response Standard (HAZWOPER) as specified

by 1910.120(a)(1)(i-v) and 1926.65(a)(1)(i-v). For more information link to: http://www.osha.gov/html/faq-hazwoper.html

- Coordinating SCAT activities
- Developing the SCAT process that would meet the objectives of the Unified Command and the data collection/documentation requirements of the Natural Resource Damage Assessment (NRDA) teams.

- Establishing on-scene Geographic Information System (GIS) mapping capabilities to capture SCAT results and provide information to Situation Unit and stakeholders

- Coordinating with the Responsibility Party's spill management team to ensure that SCAT information is shared with their scientific personnel

Wildlife Team

The Wildlife Team within the Planning Section is responsible for developing guidelines and advising on wildlife issues including but not limited to; wildlife protection strategies, capture techniques, handling of wildlife, handling of carcasses, and the employment of hazing measures. This team works closely with the Wildlife Branch within the Operations Section to minimize wildlife injuries. The Wildlife Team should:

- Ensure all wildlife recovery personnel are properly trained and authorized to capture and handle wildlife and are adhering to accepted or incident-specific health and safety guidelines.

- Ensure wildlife capture plans outline incident specific techniques to be utilized in the approved plan.

- Advise FOSC of the presence of any federally or state-listed species, and/or their supporting habitats.
    - Make recommendation to minimize or avoid adverse impacts to the species or the supporting habitat, in coordination with the appropriate Endangered Species biologists [Link to Fish and Wildlife Protection Options Section 9738]
    - Assist the FOSC with initiation and implementation of emergency consultation under the Endangered Species Act as warranted

- Advise FOSC of the presence of populations of migratory birds, sensitive species and/or their habitats and offer recommendations to minimize or avoid adverse impacts

- Mobilize federal and/or state wildlife personnel for oversight or to assist in the collection or capture of oiled wildlife [Link to Wildlife (bird) Recovery Operations/Procedures Section 9739]

- Prepare a written oiled Wildlife Recovery Plan to include, but not limited to:
    - Establishment of a hotline to report oiled wildlife
        - Establish process to ensure hotline information gets to Situation Unit and Wildlife Recovery Unit
    - Advising cleanup contractors of wildlife reporting and recovery protocols
    - Ensuring stabilization and rehabilitation protocols adhere to published guidelines accepted by federal and state natural resource managers
    - Establishing protocols to report daily wildlife numbers to the UC
    - Establishing protocols for:
        - Wildlife survey and assessments
        - Capture and transportation of wildlife
        - Deterrence of clean wildlife from an impacted environment
        - Carcass collection and processing of dead wildlife
    - References:
        - Best Practices for Migratory Bird Care During an Oil Spill Response (USFWS)
        - Best Practices for Marine Mammals (NOAA)

- Provide technical assistance in the prioritization of sensitive areas for clean-up

- Provide technical assistance to minimize or avoid adverse impacts to trust species or lands held by any State, Tribes or the United States

- Ensure the Wildlife Rehabilitation Group is aware of the clean up products used on wildlife and that the Material Safety Data Sheets (MSDS) for each product is provided

- Provide support information to Situation Unit and Public Affairs on wildlife information

- Identify release locations

- Provide technical assistance on clean-up end points and shoreline assessment techniques

- Establish and maintain a Wildlife Impact Status Database to document and track impacted wildlife from impact to grave/release

- Prepare a daily Wildlife Branch summary for the Unified Command

- Prepare a Wildlife Branch demobilization plan

- For potential support resources consult the Fish and Wildlife Response Facilities and Resources in Section 9743 [Link to Section 9743]

Sign Off Team (SOFT)

The Sign Off Team is responsible for providing documentation to the Unified Command stating that areas impacted by the oil spill have been cleaned to agreed upon standards. SOFT members usually include representation from the State, local land trustee managers, Coast Guard, Scientific Support Coordinator and the responsible party. SOFT responsibilities include:

- Evaluating areas identified by Operations as 'clean' to ensure that the agreed upon cleanup endpoints are met or "no further action is required" at a particular location
- Working with Operations to identify areas that require further cleaning
- Providing signed documentation to the Unified Command that the area evaluated met the cleanup standard [Link to Sec. 9797 Shoreline Sign Off Example]
- Coordinating any field activities with the Operations Section Chief
- Providing Documentation Unit Leader with the original copy of the SOFT Documentation

Technical Specialists

Technical Specialists may function in the Planning Section or anywhere their skills are needed in the Response Organization. They should report to the Planning Section prior to going to their response assignment.

Disposal Technical Specialist

The Disposal Technical Specialist is responsible for developing a Waste Disposal Plan that meets the requirements of municipal, state and federal regulations. Specific responsibilities include:

- Contact Operations Section Chief to assess disposal needs for types and magnitudes of materials to be handled
- Identify available tankage for interim recovered liquids storage and location(s) for interim storage of solid wastes and tank waste accumulations at each location
- Prepare a Waste Disposal Plan and submit to the Planning Section Chief and Operations Section Chief for review [Link to Waste Disposal Plan 9782]
- Contact appropriate waste transportation contractors to determine capabilities and availability

- Designate liquid waste transfer locations and ensure compatibility of equipment with vacuum/tank trucks and/or skimmers/barges

- Ensure accurate waste accounting and tracking systems are in place

- Make initial determination on hazardous nature of material through knowledge of material spilled and/or chemical analyses

- Contact potential waste treatment and disposal facilities to determine acceptance criteria and any additional characterization/testing requirements

- Collect representative samples of oil/oily wastes if required by the treatment or disposal facilities for additional characterization

- Waste should be segregated:
    - Oil and oil water mixtures recovered from the water and shoreline
    - Oiled organic debris (wood, aquatic vegetation)
    - Oiled sorbents (pads, booms, snares, sweeps)
    - Oiled sediments
    - Oiled PPE, containment boom, general trash
    - Non-oiled and non-hazardous waste materials

- Document all waste collection, segregation, handling, transportation, and treatment/disposal activities to enable accurate tracking and ensure regulatory compliance

- Consult the General Waste Containment and Disposal Checklist [Link to Disposal Checklist 9781]

Other Technical Specialist Technical specialist can be added to the response organization as necessary. The below is not an all inclusive list [Link to Technical Specialist phonebook].

- Wetland Ecology – Freshwater Tidal Wetlands

- Wetland Ecology – Salt Marshes

- Conservation Biology

- Water Quality – Contaminants, Toxicologists

- Water Quality – Biogeochemistry

Natural Resource Trustees

- Natural Resource Trustees generally serve as key advisors, rather than as designated representatives on Unified Command

- Trustees need to immediately select a Federal Administrative Lead to represent the Trustees to the Unified Command

- The lead trustee should coordinate their concerns through the Liaison Officer. If there is no Liaison Officer, the lead trustee must coordinate directly with the Unified Command

Historic Property Specialist

- Assesses potential effects of emergency response strategies on archeological/historic properties in consultation with the parties identified in the ACP

- Recommends to the FOSC response actions and policies developed in consultation with parties identified in the ACP to help minimize potential impacts to historic properties

Marine Transportation System Recovery Unit (MTSRU)

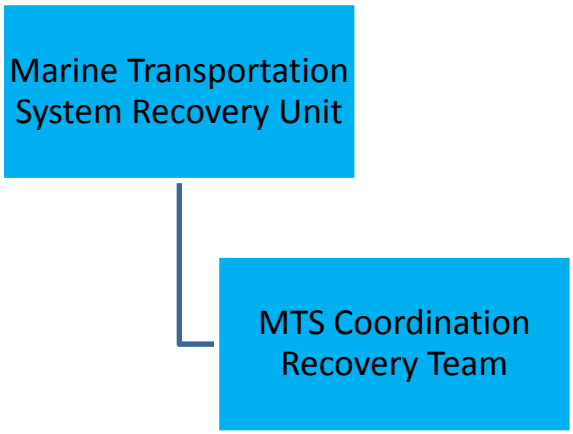

Figure 6. New Marine Transportation System Recovery Unit

The Marine Transportation System Recovery Unit is responsible for planning infrastructure recovery as a result of incidents that significantly impact the marine transportation system.

The MTSRU function during an oil spill is to identify gaps, evaluate the incident and report possible courses of action to reduce the impact on the marine transportation system. This is done by utilizing the MTSRU Recovery Coordination Team.

In addition, the MTSRU will report the conditions of the port to CG District 5 and HQ simultaneously, to ensure an accurate "on the spot" report. Common Assessment Reporting Tool (CART) system has been pre-loaded with the current port condition under normal operations, known as Essential Elements of Information. A few examples of "EEI's" are waterways availability, facilities within the AOR, domestic vessel operations, and oil spill

activity within the AOR. The system enables the IC to track the progress of certain operations and utilize this data to assign priorities for the next operational period.

Marine Transportation System Recovery Coordination Team (Formerly - Facility and Vessel Decontamination Prioritization)

The MTSRU Coordination Team is responsible for supporting the Waterways Management Unit's efforts to prioritize the decontamination of commercial facilities and vessels. The information provided by this Team is one of several variables used in the final determination. Primary responsibilities include:

- Assemble port partners from the maritime industry to determine the variables (i.e. type of cargo, impact on community, etc.) to be used when prioritizing decontamination. Port partners may include but not limited to:
    - Delaware Bay and River Pilot's Association
    - Mariner's Advisory Committee
    - Maritime Exchange
    - Delaware River Maritime Enterprise Council
    - Philadelphia Regional Port Authority
    - Delaware River and Bay Authority
    - Representative sample of port facilities impacted by the spill
- Develop a mathematical model based on the economic impact that would result from delaying a return to normal operations [Link to sample Facility and Vessel Decontamination Priority Model Section 9748]
- Use the results of the model to rank order facilities and vessels
- Provide ranked outcome to Waterways Management within Operations to assist with their scheduling of facilities and vessels for decontamination.
- Approve or disapproves vessel movement based on the following criteria:
    - Cargo prioritization
    - Location of oil spill
    - Tides
    - Berth availability
    - Vessel determined to be clean by the Decontamination Group
    - Facility piers determined to be clean by the Decontamination Group
    - Transit times
    - Vessel movements through or within the safety zone(s)
- Coordinate all vessel arrivals, departures, and request from vessels to shift berths [Link to the Commercial Vessel Traffic Movement Criteria Section 9730]

- Instructions for vessels requesting entry into the safety zone [Link to sample Entry Instruction Section 9731]
- Instructions for vessels requesting to shift berths within the safety zone [Link to sample Shifting Instruction Section 9732]
- Instructions for vessels requesting to depart the safety zone [Link to sample Departure Instruction Section 9733]

- Coordinate vessel movements with the Safety Zone Enforcement Group

- Provide the following information to the Situation Unit and the Marine Transportation System Recovery Unit, if established, prior to the Unified Command Planning Meeting:
  - Number of vessels awaiting berth
  - Number of vessels authorized inbound transit through the safety zone
  - Number of vessels departed
  - Number of vessels awaiting decontamination
  - Number of vessels actively being decontaminated
  - Total number of vessels decontaminated
  - Number of vessels awaiting inspection
  - Total number of vessel inspections completed

Volunteer Coordinator or Unit (as necessary)

Volunteers may want to participate in a spill response. As such, the response organization has to prepare for their arrival. Depending on various factors, the UC, may mange the volunteers utilizing a Coordinator, Unit or Officer position. Available tools to manage them include:

- Section 4300 of the Sector Delaware Bay ACP
- Guideline developed by the National Response Team (NRT)
- MOU - USCG, EPA & Corporation for National and Community Service

Finance Section Organization

The Finance Section is responsible for all financial, administrative and cost analysis aspects of the incident. Utilize the U.S. Coast Guard, Incident Management Handbook and Finance Section Chief Job Aid to build the appropriate Finance Section.

Finance Section Chief:

The FSC may have Deputy FSC's, who may be from the same agency or from an assisting agency. USCG District 5's, District Response Advisory Team (DRAT), may be able to provide expertise and technical assistance to the FSC during oil spills. Request the DRAT resources through the District 5 Command Center. Additionally, the USCG's Director of Operational Logistics (DOL) provides mission support logistics during contingency operations. Contact DOL for available resource support.

Finance Section Chief References:

- Various ICS Position Job Aids for positions or "tools" normally found in or used by the Finance Section can be found on the Coast Guard's HomePort website (HomePort> Library> Incident Command System ICS>)

Ensure that Pollution Removal Funding Authorizations (PRFA) are completed for agencies providing response assistance.

Logistics Section Organization

The Logistics Section Chief is responsible for providing facilities, services, and material in support of the incident. Utilize the U.S. Coast Guard, Incident Management Handbook and Logistics Section Chief Job Aid to build the appropriate Logistics Section.

Logistics Section Chief

The LSC may have Deputy LSC's, who may be from the same agency or from an assisting agency.

Logistics Section Chief References:

Coordinate with the Operations Section Chief on dispersant requirements [Link to Dispersant and Equipment Sources Section 9746]

Special Teams

The following are some of the agencies, special teams and other technical experts that can be utilized during a spill response:

- National Oceanic Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC)
- National Strike Force Atlantic Strike Team
- National Strike Force Public Information Assist Team
- NOAA National Marine Fisheries Service
- NOAA Navigational Response Team (access through NOAA SSC)
- Coast Guard Atlantic Area Incident Management Assist Team
- Coast Guard Public Information Assist Team
- District 5 District Response Advisory Team (DRAT)
- District 5 Public Affairs Detachment
- EPA On-Scene Coordinators from Region II and III
- Environmental Protection Agency (EPA) Environmental Response Team
- Navy Supervisor of Salvage [Link to NAVSUPSALV example request message Section 9745]

Example of Real-World Clean-up Endpoints

9737 Example Cleanup Endpoints (ATHOS I Oil Spill 2004)

Conduct cleanup with minimal damage to environmental resources. i.e. Do not drive spilled oils into sediments by foot / mechanical traffic

A SCAT Special Issue Team (SIT) will evaluate historic, special environmental, or high-public access areas to provide more detailed and additional cleanup requirements.

Shoreline Type	Cleanup Endpoint	Allowable Cleanup Methods
Sand Flats (hard surface e.g. Tinicum I. NJ side)	General: No recoverable surface oil, buried oil layers or tarballs larger than dimes; no more than stain on sand	Manual removal with shovels/rakes and squeegees; small equipment (bobcat) to remove oil and oiled surface and subsurface sand; minimize removal of clean sand on and under oiled layers; Minimize equipment (bobcat) travel over oiled surfaces.
	Special: TBD by SIT (Special Issue Team)	
Sand Beaches; Mixed Sand and Fine Gravel Beaches	General: No recoverable surface oil, buried asphalt pavements or tarballs larger than dimes; no more than stain on gravel	Manual removal with shovels/rakes; minimize removal of clean sediments on/under oiled layers; small equipment (bobcat)to remove oil and oiled surface/subsurface sand and gravel. Minimize small equipment (bobcat)travel over oiled surfaces. Mechanical relocation of fine gravels into piles for flushing, including use of high-pressure/hot-water washing (hotsie), with containment/recovery of released oil; return gravel to original location and contour. Use of heavy equipment will require additional approval.
	Special: TBD by SIT	
Course Gravel Beaches/Fill (e.g. cobbles, and larger)	No more recoverable or potentially mobile oil on surface, doesn't rub off on contact Visible heavy product that could be mobilized should be removed.	Manual removal of surface oil using low pressure flushing and high-pressure/hot-water washing (hotsie), with containment/recovery of released oil; return gravel to original location and contour. Use of heavy equipment will require additional approval by the SIT.
	Special: TBD by SIT	
Riprap/Stone Seawalls **Solid Seawall, Bulkheads and Docks**	General: No more recoverable or potentially mobile oil on surface, doesn't rub off on contact Visible heavy product that could be mobilized should be removed.	Flushing and high-pressure/hot-water washing (hotsie), as needed. Containment/recovery of released oil.
	Special: No more recoverable or potential mobile oil on surface; Stop cleanup efforts when all oil is removed other than a stain. Additional cleaning or replacement of riprap to be considered by SIT.	In high-public access or special environmental / historic areas (e.g., Ft. Mifflin, eagle nesting, others to be determined): may request use of SWAs (surface washing agents) or special cleanup efforts for use as need to meet endpoint.

9737 Example Cleanup Endpoints (ATHOS I Oil Spill 2004)

Mud Flats (e.g. soft surface, steps will push oil in sediments)	General: No potentially mobile oil.	To be determined on a site-specific basis by SIT.
Marshes	General: Oil on vegetation no longer wipes off on contact. No remaining recoverable or potentially mobile oil in accessible areas. (Accessible areas will be identified by SIT.)	To be determined on a site-specific basis by SIT. Options (cutting, In-situ-Burn, flushing, manual pickup of pooled oil, monitoring) to be determined on site-specific basis.
	Special: Other removal options will be considered by Environmental Unit.	

Debris Recovery Guidelines[1]

- Report dead and live wildlife to triage center at 215-365-1558. Collect and bag all dead wildlife.
- Manual removal of oiled debris that can be easily picked up and bagged.
- For small unoiled debris that can be easily picked up, move to the supra tidal zone if it has the potential to become oiled in its current location.
- Leave unoiled debris in place if it does not have the potential to become oiled.
- Cut and remove oiled logs < 6 inches in diameter (cut in into lengths < 6 feet).
- Manual removal of oiled debris (other than logs) < 6 inches in diameter and < 6 feet in length.
- Clean large (> 6 inches in diameter and/or 6 feet in length) oiled debris in place. Recover oil using appropriate sorbents. Approved cleaning methods for large oiled debris are presented below:

Method	Handling	RRT Approval	Special Permits
Scraping	No	No	No
Wiping	No	No	No
Hotsie	No	No	No

The following options require special approval

Method	Handling	RRT Approval	Special Permits
SWAs	No	Yes	No
Burning	Yes	Yes	Yes

For questions regarding environmental issues, contact the Environmental Unit Leader.

Oil Spill Observation Checklist

9741 Oil Spill Observation Checklist

Record your observations of spilled oil either in a notebook or directly on a chart of the area under observation. Here is a checklist for organizing your observations.

General Information

___ Date

___ Time

___ Case name

___ Observers' names

___ Observers' affiliations

___ Location of oil's source (if known)

___ Stage of tide (flood, ebb, slack)

___ On-scene weather (wind, sea state, visibility)

___ Platform (helicopter, fixed-wing aircraft, boat)

___ Flight path/track line

___ Altitude where observations taken

___ Areas not observed (e.g., foggy locations, restricted air spaces, shallow water areas)

Note: When following a flight path or track line, travel beyond known impacted areas to check for oil beyond these areas and to minimize the number of observations made while facing into the sun.

Note: Include the name and phone number of the person making the observations.

Oil Observations

___ Slick location(s)

___ Slick dimension(s)

___ Orientation of slick(s)

___ Distribution of oil (e.g., as windrows, streamers, pancakes, or patches)

___ Color and appearance (e.g., rainbow, dull or silver sheen, black, or brown in color, or mousse)

___ Percent coverage (see Percentage Coverage Chart)

___ Is oil recoverable (Y/N)? (examples of recoverable oil types include black oil, mousse, and heavy dull- or dark-colored sheens)

Note: Clearly describe the locations where oil is observed, as well as the areas where no oil has been seen.

Other Observations
Response Operations...

___ Skimmer deployment (general locations where skimmers are working. Are they working in the heaviest concentrations of oil?)

___ Boom deployment (general locations of boom(s). Does the boom contain oil? Is oil entraining under the boom?)

___ Source of oil (describe the status of the source. Is oil still being released?)

Environmental Observations...

___ Locations of convergence lines, rip tides, and sediment plumes

___ Locations of kelp beds, sea grass beds, and other features that could be mistaken for oil

___ Wildlife present in area (locations and approximate numbers of birds and marine mammals)

Revised: July 17, 2001
Office of Response and Restoration, National Ocean Service, National Oceanic and Atmospheric Administration

APPENDIX 1 – Maps showing the results of the submerged oil monitoring

SUBMERGED OIL ASSESSMENT – ATHOS 1 OIL SPILL

I. INTRODUCTION

At 9:30 pm on 26 November, the *T/V Athos* 1 struck a submerged object while preparing to dock at the Citgo facilities, resulting in two holes in the No. 7 port and center tanks. It was carrying a heavy Venezuelan crude oil. The initial report was that 30,000 gallons were released; on 30 November, the volume was increased to a maximum potential of 473,500 gallons. The final estimate will be available once the oil from the holed tanks has been offloaded from the tanker.

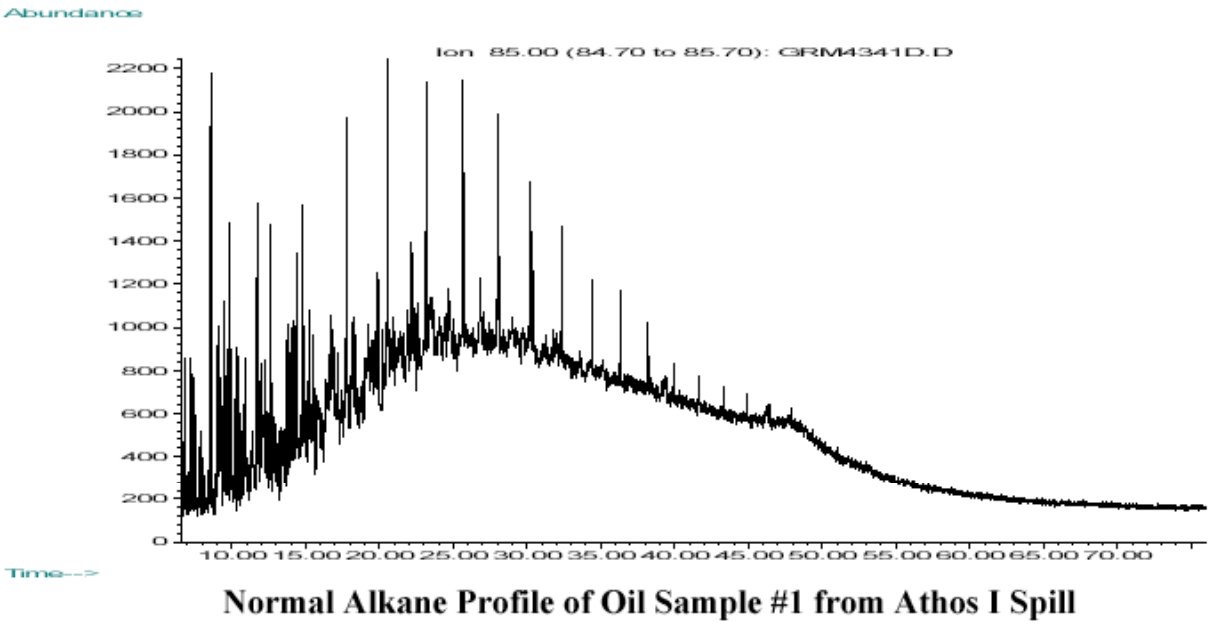
There was concern that some of the heavy oil would mix with sediment and not float. Pooled oil was reported on the bottom at the collision site, and shoreline assessment teams reported that oil stranded on the intertidal zone had started to become submerged during the rising tide. Therefore, the Unified Command formed a Submerged Oil Assessment Task. The Submerged Oil Task Force, comprised of members from The O'Brien Group, U. S. Cost Guard, and the National Oceanic and Atmospheric Administration, was assigned to assess the extent and degree of submerged oil and develop recovery options. The Salem Nuclear Power Plant started shutdown procedures for the No. 2 unit on 3 December and No. 1 unit on 4 December because of the threat of oil contamination of the circulation and service water intake systems. The Logan Power Plant in New Jersey stopped using water from the river for a day. Other utility and industrial water intakes along the river have been concerned about the impacts on the oil on their water intakes and water use within the facility, though none have reported shut-downs. The submerged oil also posed risks to shellfish resources in Delaware Bay.

II. CHARACTERISTICS OF THE SPILLED OIL

A. Physical Properties of Source Oil

Two samples of the oil from hold No. 7 center (the source oil) were analyzed for physical properties and chemical characteristics, with the following results:

- Density: 0.973 and 0.978 grams per milliliter; fresh water is 1.00 and oceanic sea water is 1.025 g/ml. Therefore, the oil is lighter than both fresh water and sea water.
- Viscosity: greater than 5,000 centiStokes (cSt) at 100°F and at ambient water temperature greater than 50,000 cSt, meaning that the oil's viscosity is similar to cold honey;
- Composition: the oil is composed of a large amount of asphaltenes and other high molecular weight compounds. The aromatic hydrocarbon content is very low (0.06%), and the oil has a very low dissolved fraction. Figure 1 is the normal alkane distribution in the fresh oil. Note that there are few individual peaks and a large "hump" of unresolved hydrocarbons. This oil can be characterized as a heavy, degraded crude oil.



Normal Alkane Profile of Oil Sample #1 from Athos I Spill

Figure 1. Normal alkane profiles of the source oil from hold No. 7 center. Note there are few identifiable peaks and a large "hump" of unresolved compounds.

B. Behavior of the Spilled Oil

One of the key concerns was whether the oil would not float after release to the environment and loss of the light fractions due to evaporation. The fresh source oil was "evaporatively weathered" by heating it to 90°C under vacuum and less than 3 % was lost by evaporation after 4 hours. Therefore, the weathered oil (after evaporation) is still expected to float. Using the National Oceanic and Atmospheric Administration (NOAA) oil weathering model ADIOS, up to 13% of the oil could have evaporated within 5 days of the release. Based on the chemical analysis and model results, the amount of oil lost via evaporation is likely 3-13%.

With only 0.06% aromatic hydrocarbons (which are the primary compounds in the oil that dissolve), lost via dissolution was estimated as less than 1%. The oil is very viscous and did not form a stable emulsion even when exposed to high wave energy. The model ADIOS estimated less than 1% of the fresh oil dispersed into the water column. The Delaware River contains a high suspended load, but due to the viscous nature of the oil, very little of the oil (less than 1%) adhered to particles in the water column (as opposed to sandy sediments on the shoreline).

While the exact amount released is unknown, the amount lost to oil weathering processes (evaporation, dissolution, emulsification, dispersion, and adsorption to suspended particulate matter) is likely tens of thousands of gallons (Table 1).

The shoreline cleanup assessment teams provide some indication of the length of shoreline oiled. However, the technology does not exist to accurately measure shoreline thickness. This information is needed to calculate oil volume. The amount of oil recovered from the shoreline is mixed with debris and sediments, and the oil content of the oily waste is unknown.

As discussed later, some of the oil that stranded on the shoreline picked up sediment. Samples collected from the oil stranded on the shoreline and recovered from the water column had a few % sand. Even 2-3 % of sand is enough to make the oil slightly heavier than fresh water.

A preliminary mass balance of the spilled oil is shown in Table 1.

Table 1. Preliminary mass balance of the spilled oil.

Physical Process	Estimates
Evaporation	3 – 13% of total volume spilled minus volume of oil in trench #1 and #2
Dissolution	< 1% of total volume spilled
Emulsification	0%
Dispersion	1% total volume spilled
Sedimentation (due to river load)	Unknown but likely < 1%
Oil on shoreline	~ 100 miles
Oil recovered from shoreline	Unknown
Oil floated off shoreline	Unknown
Oil with sediment mobilized off shoreline	Unknown
Tarballs in water column	Unknown
Tarballs on bottom	Unknown
Pooled oil (located in Trench #1 and #2)	~ 4000 gallons

III. PHYSICAL PROCESSES AND TRANSPORT

A. Oil Trajectory and Physical Processes during the Spill

The primary forcing function for currents in both the Delaware River and Bay are the semidiurnal tides. Near the spill site, maximum currents are about 2 knots with a tidal excursion of about 8 miles. In the middle of Delaware Bay, maximum currents are about1 knot with a tidal excursion about 4 miles. The river inflow into the system results in a net displacement down river over each 12 hour cycle. The currents from the river outflow are small compared to the tidal currents but it is the major factor in any net down river displacement of subsurface oil.

Water levels in the River and Bay rise and fall as function of onshore/offshore winds. This can raise the water levels in the river 1 – 2 feet above or below predicted tide levels. Severe storm events, much stronger than reported during the spill event and more intense than the usual storm, could have a significant effect on the currents and oil transport.

In the Chesapeake – Delaware Canal, the tide wave moves from the Chesapeake into the canal towards Reedy Island in the Delaware River. Water level differences between Chesapeake Bay and Delaware River due to meteorological events and river discharge can result in water flowing from the Delaware into the Chesapeake.

For the most part, the River and Bay are well mixed vertically. The U.S. Environmental Protection Agency collected salinity measurements from the spill site to Raccoon River entrance and reported values of 1 to 2 ppt. In addition, NOAA measured salinity and conductivity near the Commodore Barry Bridge, which indicated the river, was well mixed. There is a broad salinity gradient or mixing zone in the lower river and in the bay. The gradient of mixing in winter and spring is largest near Ship John Lighthouse (39° 19'N, 75° 23'W). The gradient moves seaward with increases freshwater. The interface between the freshwater and saline water may be a collection area for floating oil. Since the mobile subsurface oil contains sediment, the density differences along the saltwater – freshwater mixing zone are less likely to cause submerged oil to refloat.

Outside the Bay, the circulation on the inner continental shelf is primarily controlled by winds and water density differences. Off the northeast coast, freshwater input from rivers such as the Hudson and Delaware result in a near shore density flow from the north to south. Currents due to density differences in the water will be within 10 miles of the shoreline, follow the shoreline and typically move to the south at speeds between 0.1 and 1 knot. Superimposed are the regional winds, which will generate a coastal current to the north with southerly winds and southward with northerly winds. At the Bay entrance, there is a net flow of fresh water along the south side and net inflow along the bottom of the north side.

Initially, the spill formed a thick film and moved upriver with the flood tide. A southeast wind moved oil to the Pennsylvania side of the river. With the second flood tide, the oil was transported as far north as the Petty Island area. Several days later, stronger winds transported oil to the New Jersey side. After the storm, the oil weathered and formed tarballs. By 28 November, oil extended down river to the Delaware Memorial Bridge. Overflight observations of the floating oil have consistently been within the uncertainties of the NOAA trajectory model predictions. The 24-48 hour forecasts of the floating oil will continue until the overflight observer is no longer able to detect the leading edge of the spill.

B. Long-term Transport

With the type and quantity of oil spilled, tarballs are expected to persist for several months in the Delaware River system. Over the next few weeks, scattered tarball are expected to contact shoreline anywhere along Delaware Bay. There is a possibility of oil movement through the Chesapeake – Delaware Canal into upper Chesapeake Bay. The exact location and amount of oil depends on the wind, oil fate, and amount of oil mobilizing upstream. Within several weeks of the initial spill, tarball contact is anticipated along the outer coast. The mean current along the outer coast is southward and anticipate most of the contacts south of Delaware Bay. Local wind events could push tarballs to the north up to 50 miles north of Cape May and as far south as the entrance to Chesapeake Bay. While the general trend for the number of tarballs contacting the outer coast is expected to decrease within a month or two, the amount of subsurface oil in the Delaware River remains unknown. Thus, there remains a possibility that a strong meteorological event or vessel movement could mobilize oil resulting in an episodic increase of tarballs.

IV. SPILL INFORMATION

A. Floating Oil

Weather permitting, overflights of the spill area have shown a general decline in floating oil. Observer have reported mostly scattered sheens with tarballs ranging from < 0.5 cm (pea size) to about 20 cm (dinner plate). The few exceptions occurred when the on-scene winds were calm or at slack tide. Without any waves or strong tidal mixing to disperse the sheening tarballs, large areas of continuous sheens were reported from the observers. Any increase in the wind generated waves dispersing the sheens. Without associated sheens, it is extremely difficult to track the tarballs. A decrease in the wind speed or at slack tide would allow the observer to once again see the sheens. This pattern repeated itself several times during the spill event. Finally, observers indicated that some of the tarballs had weathered to the point of not sheening.

For the long term, tarballs are very persistent in the environment and can travel hundreds of miles. They are expected to move out of Delaware Bay and through the C&D Canal into the upper Chesapeake Bay. Natural collection areas, such as the surface interface between the freshwater and saltwater and convergence zones on ebb tides, are good locations for finding the tarballs. If tarballs appear on the shoreline, it is likely they were nearshore, difficult to detect and onshore winds brought them ashore.

B. Non-floating Oil

a. Pooled Oil

i. Survey Methods

Pooled oil is defined as oil that has accumulated in depressions and is not readily mobilized by normal riverine and tidal currents. Both NOAA and EPA used different sonar systems to detect areas of pooled oil. Experts from NOAA, EPA, and Navy Supervisor of Salvage reviewed these data and determined the systems could not identify pooled oil. Therefore, coring and sorbent probes were used to search for pooled oil in likely accumulation areas. The US Army Corps of Engineers bathymetric maps of the channel and adjacent areas (generated from data obtained on 5 December 2004) were used to identify targets for the pooled oil survey teams. Divers were also used to observe areas where pooled oil was found. The locations that were searched for pooled oil included:

- The shallow bay north of Tinicum Island, including two deep depressions
- Four depressions on the south side of the channel across from Tinicum Island (Tinicum Range channel)
- Tinicum Range channel
- Shallows around Chester Island

ii. Locations

Pooled oil was found only at the collision site, in a trench described as 6-8 ft wide, 2 ft deep, and 41 ft long. On 9 December, a diver surveyed the trench area and measured the oil thickness as between 1.5-2 ft deep. A second trench was also detected and estimated to be 2 ft wide by 2 ft deep by 15 ft long.

iii. Volumes

The volume of pooled oil in the trenches at the collision site was estimated to be approximately 3,390-3,610 gallons, depending on the assumed oil thickness in the second trench (Table 2).

A sample of the oil from the trench (density of 0.943 g/ml) floated in fresh water. It was tested for cohesiveness and found to adhere to sediments. Based all the information available, the oil in the trench at the collision site was "injected" into the sediment under the pressure of the release, creating it's own trench. The viscous oil adhered to the sediments and not refloated, even though it should based on density. The oil is immobile due to highly cohesive forces exerted by the viscous oil.

Table 2. Estimated volume of oil on the bottom at the collision site.

Length	Trench Width (feet)	Depth of Trench (feet)	Depth of Oil (feet)	Amount of Oil (gallons)
Trench 1				
0+00	6	2	1.5	910
0+10	8	3	2	310
0+13	6	2.67	2	890
0+23	6	2.5	1.5	610
0+33	5	2.5	1.5	450
0+41	0	0	0	3,170
Trench 2				
15	2	2	If assume 1	220
			If assume 2	440

iv. Pooled Oil Recovery Methods

Several methods were evaluated for recovery of the pooled oil in the trench. The viscous oil is expected to float when disturbed, therefore special containment systems are needed. Options include:

- Diver-directed pumping systems with positive displacement pumps that can move viscous oils
- Dredging systems of different sizes
- Subsurface recovery using sorbents, either by divers or remote techniques

Divers using viscous oil pumps will begin oil recovery on 12 December. Booms and sorbents will be used to recover any floating oil; a submerged bottom filter fence will recover any oil transported in the water column downcurrent from the recovery site. The oil recovery is estimated to be completed in four days.

b. Mobile Oil

i. Survey Methods

Mobile oil is defined as oil that is negatively buoyant and subject to transport by riverine and tidal currents. It is present throughout the water column, though it appears most of the mobile oil is within a few feet of the bottom. To track the vertical distribution of the oil and the geographical extent over time, two survey methods were used:

- Snare Samplers: These samplers consist of an anchor, 50 ft of snare on a rope, and a float (shown in Fig. 2). The snares are composed of thin sheets of polypropylene, and viscous oils readily adhere to them, even under water. They are visually inspected for the presence of oil with depth, and the amount of oil is estimated as a percent coverage. The snare/rope is replaced when oiled, and they are monitored over time, weather permitting.

- V-SORS: The Vessel-Submerged Oil Recovery System (V-SORS) consists of a pipe with attached chains and snare (Fig. 3). The V-SORS is towed behind a vessel on the bottom at slow speeds. It is pulled up regularly and inspected for oil. Five V-SORS were used to both identify areas of submerged oil (including in the navigation channels where it was not possible to place the snare samplers) and to recover oil in all potential accumulation areas.

ii. Locations

Figures 4-6 shows all the locations where snare samplers were deployed at any time. The spill area was divided into three monitoring zones: MA extends from the Tacony-Palmyra Bridge to the Delaware Memorial Bridge; MB extends from the Delaware Memorial Bridge to just below the Salem Nuclear Power Plant; MC extends from the Salem Nuclear Power Plant to mid-Delaware Bay. Appendix 1 includes the results plotted for each monitoring division for the different deployment and retrieval periods. Weather and logistics prevented inspection of all snare samplers every day. In areas with strong currents, the snares would often be lost between inspections. Existing samplers in areas with strong currents are being replaced with heavier anchors, more visible buoys, and better attachment methods.

Figure 2. The snare sampler system consists of an anchor, a 50 ft string of snare on a rope, and a float. The samplers are inspected regularly and the percent oil coverage at different intervals is recorded. Most of the time, the heaviest oiling is on the bottom several feet.

Figure 3. The Vessel-Submerged Oil Recovery System (V-SORS) that is being used to search for and recover submerged mobile oil on the river bottom. The chains keep the sorbents along the bottom. The oil readily adheres to the snares underwater.

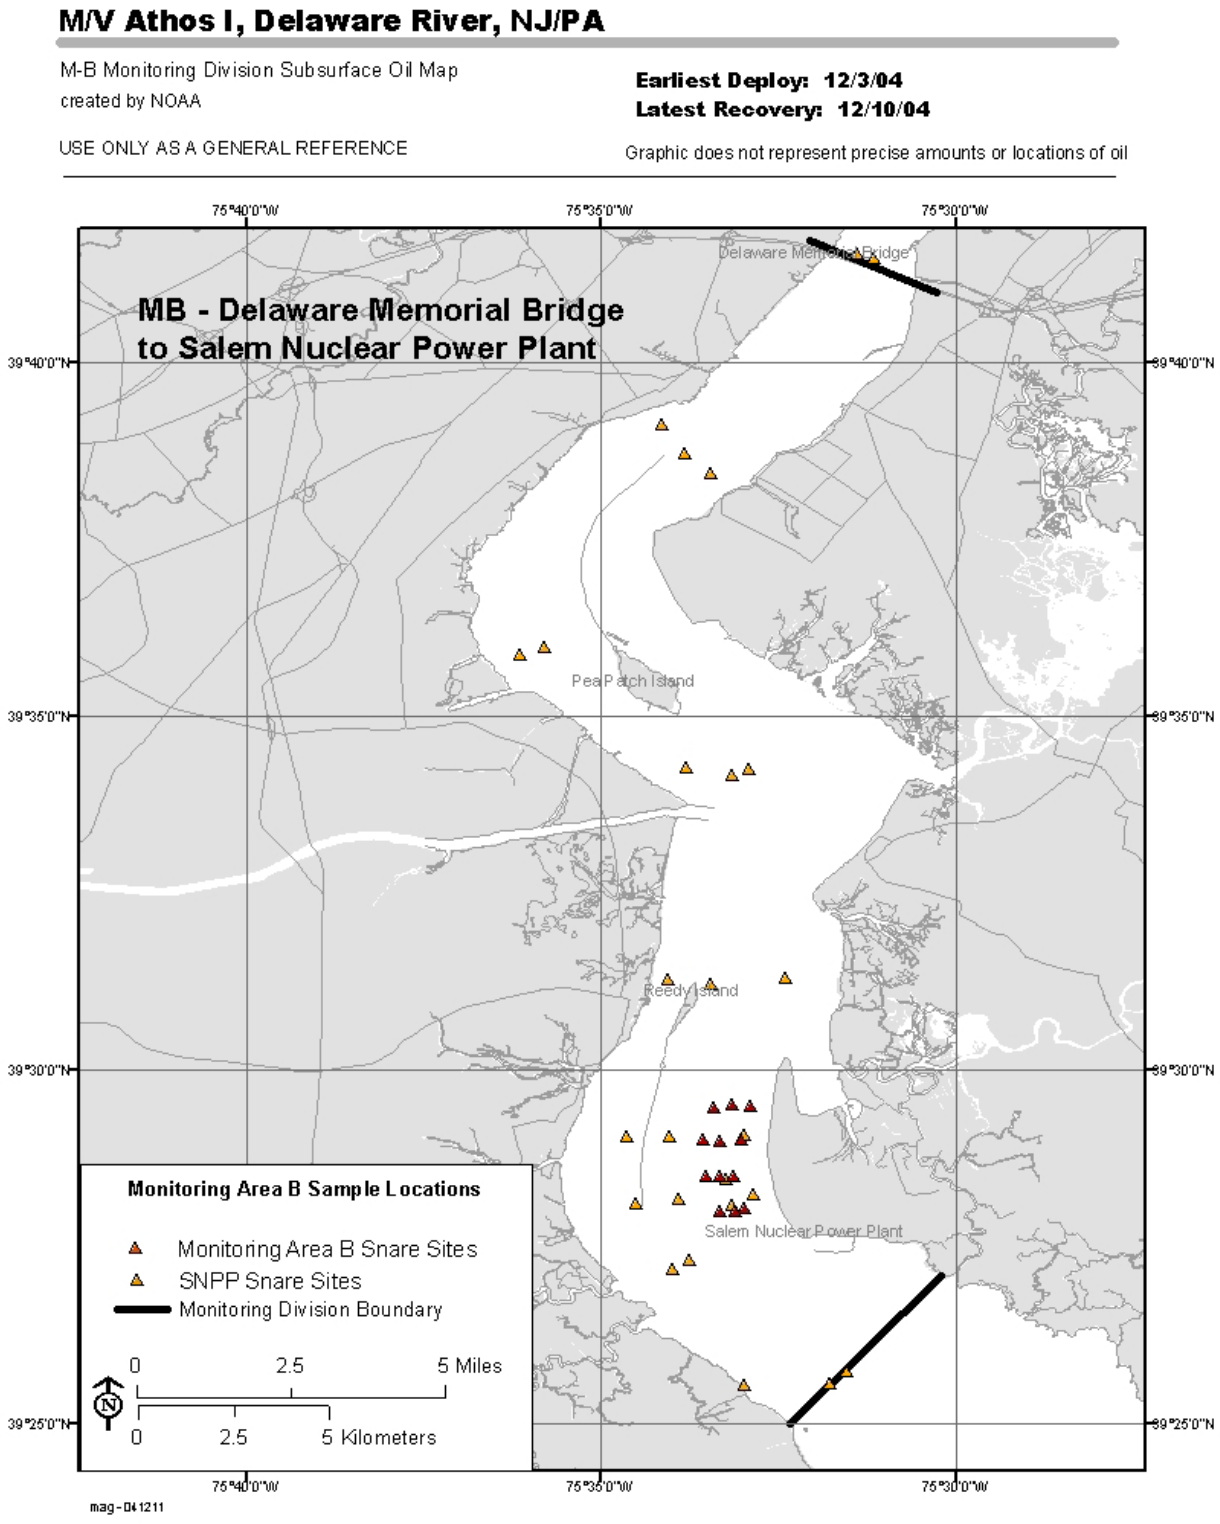


Figure 5. Location map showing the distribution of the snare sampling locations in the middle part of the spill zone (Division B).

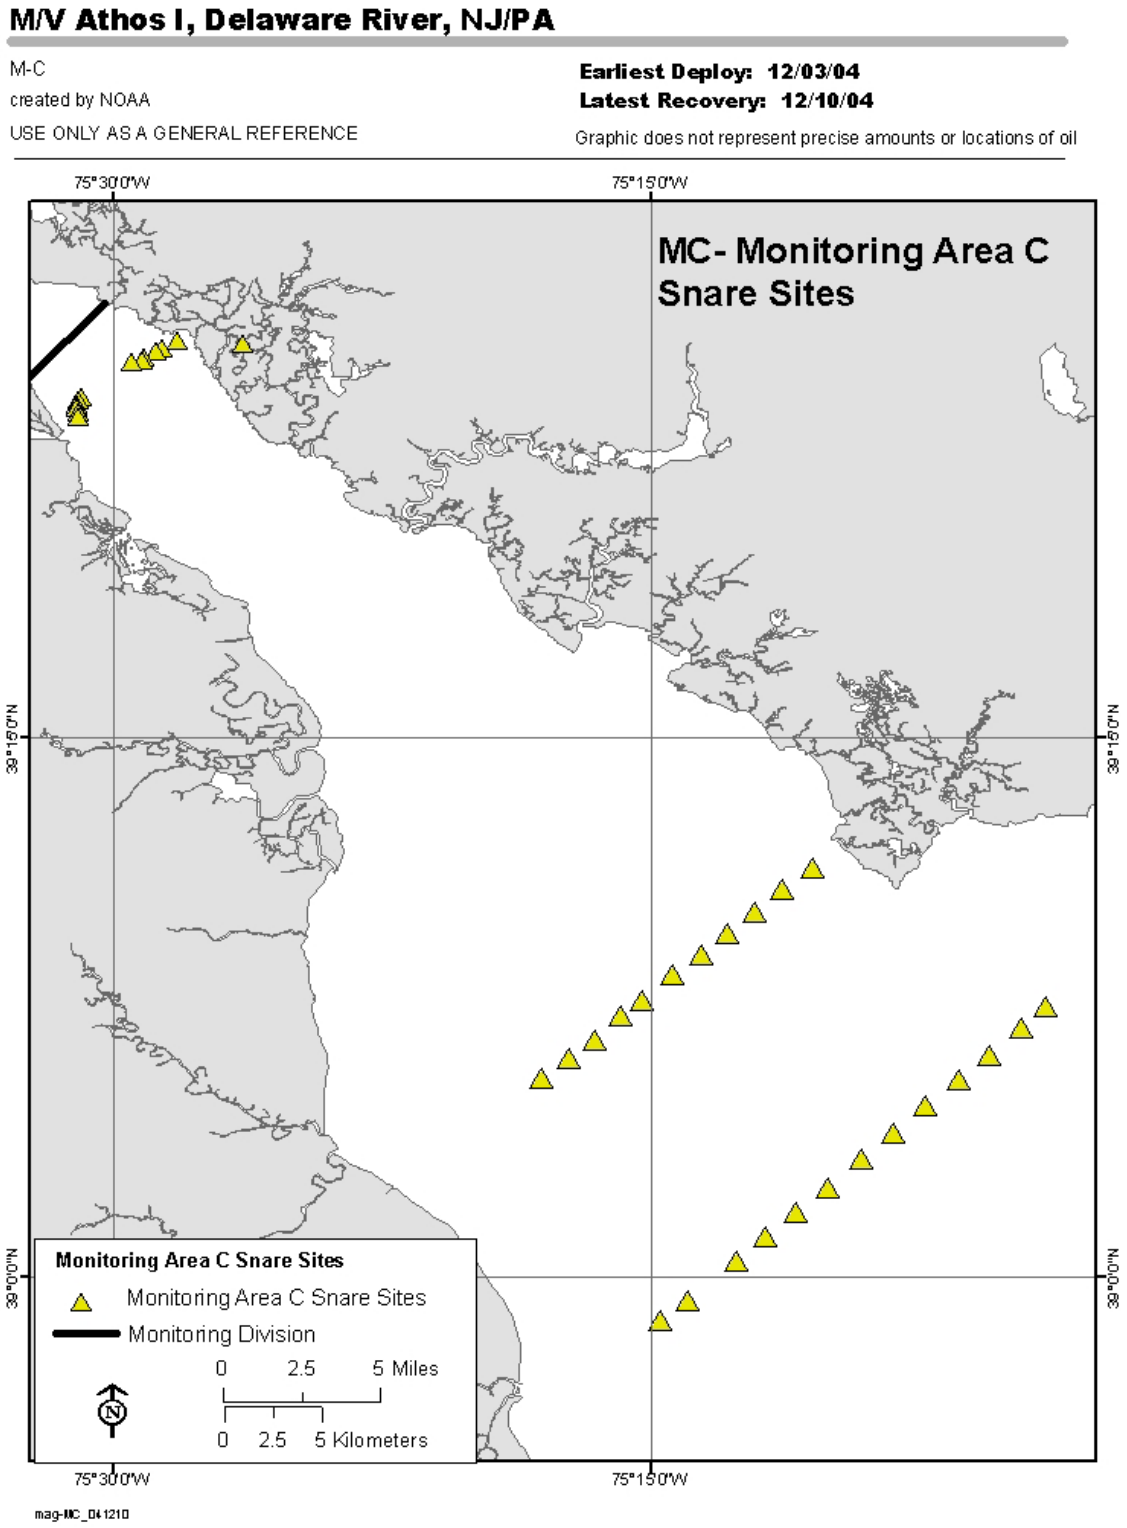

Figure 6. Location map showing the distribution of the snare sampling locations in the lower part of the spill zone (Division C).

iii. Results

Most of the submerged, mobile oil occurred several feet off the bottom, though small amounts of oil were present on the snares suspended in the middle and upper water column. Highest amounts of oil were detected around Tinicum Island. Refer to the maps in Appendix 1 for detailed data presentation for all monitoring sites. Figure 7 shows the temporal trend for station MA-1A that is located just north of Tinicum Island and consistently had the highest amount of oil on the snare. The snare was first deployed on 4 December and recovered on 5 December, and there was 50% oil coverage of the lower snares. The next day, the oil coverage was 30%. The snare was inspected two days later, on 8 December, and the coverage was 65%. For the next three days, the oil coverage was less than 15%. The steady decline for the last three days is consistent with the V-SORS tows, which also show decreasing amounts of oil recovery around Tinicum Island over the same period. There were scattered stations with high oil coverage observed on one day over the period 3-8 December. Many of the other snare samplers in the upper river never were oiled. Since 9 December, the maximum oil coverage on snares in this area was 10-15% (near Tinicum Island). It appears that the submerged oil in this upper spill zone has decreased significantly.

Figure 8 shows the temporal trend for station MB-3B, which is west of Pea Patch Island, and the detailed maps are included in Appendix 1. The distribution of the submerged oil in this area is difficult to assess because of the spotty data.

No oil or less than 1% was observed on any of the snare samplers in Division MC, which covers the upper Delaware Bay. Again, the data are spotty because many of the original stations were lost due to the strong currents in this area. However, it appears that little to no submerged oil has entered the upper bay as of 11 December.

iv. Mobile Oil Recovery Methods and Results

The V-SORS were towed in a wide range of locations that were identified as likely areas of submerged oil. The highest oil recovery was in the vicinity of Tinicum Island. Figure 9 shows the track lines of the V-SORS tows near Tinicum Island, color-coded with the amount of oil observed on the snares for each tow track. A large amount of oil stranded on the sandy tidal flat on the southern side of Tinicum Island. Oil stranded on many other shoreline areas but the shoreline types upstream of Tinicum Island are mostly seawalls, riprap, and mixed sand and gravel beaches. Tinicum Island is the main area with a largely sandy substrate. The oil is very sticky and would pick up sand, and only 2-4 % sand by weight would be enough to make the oil slightly negatively buoyant. By 30 November, oil on Tinicum Island did not re-float with the rising tide, and pieces of oil were being eroded from the shoreline by wave action. This area is thought to be the major source of the oil that became submerged and moved with the currents along the bottom of the river. Most of the oil recovered by the V-SORS was from the subtidal areas south of Tinicum Island. Very little oil was detected in the shallow area north of the island, both by the V-SORS tows and the pooled oil surveys.

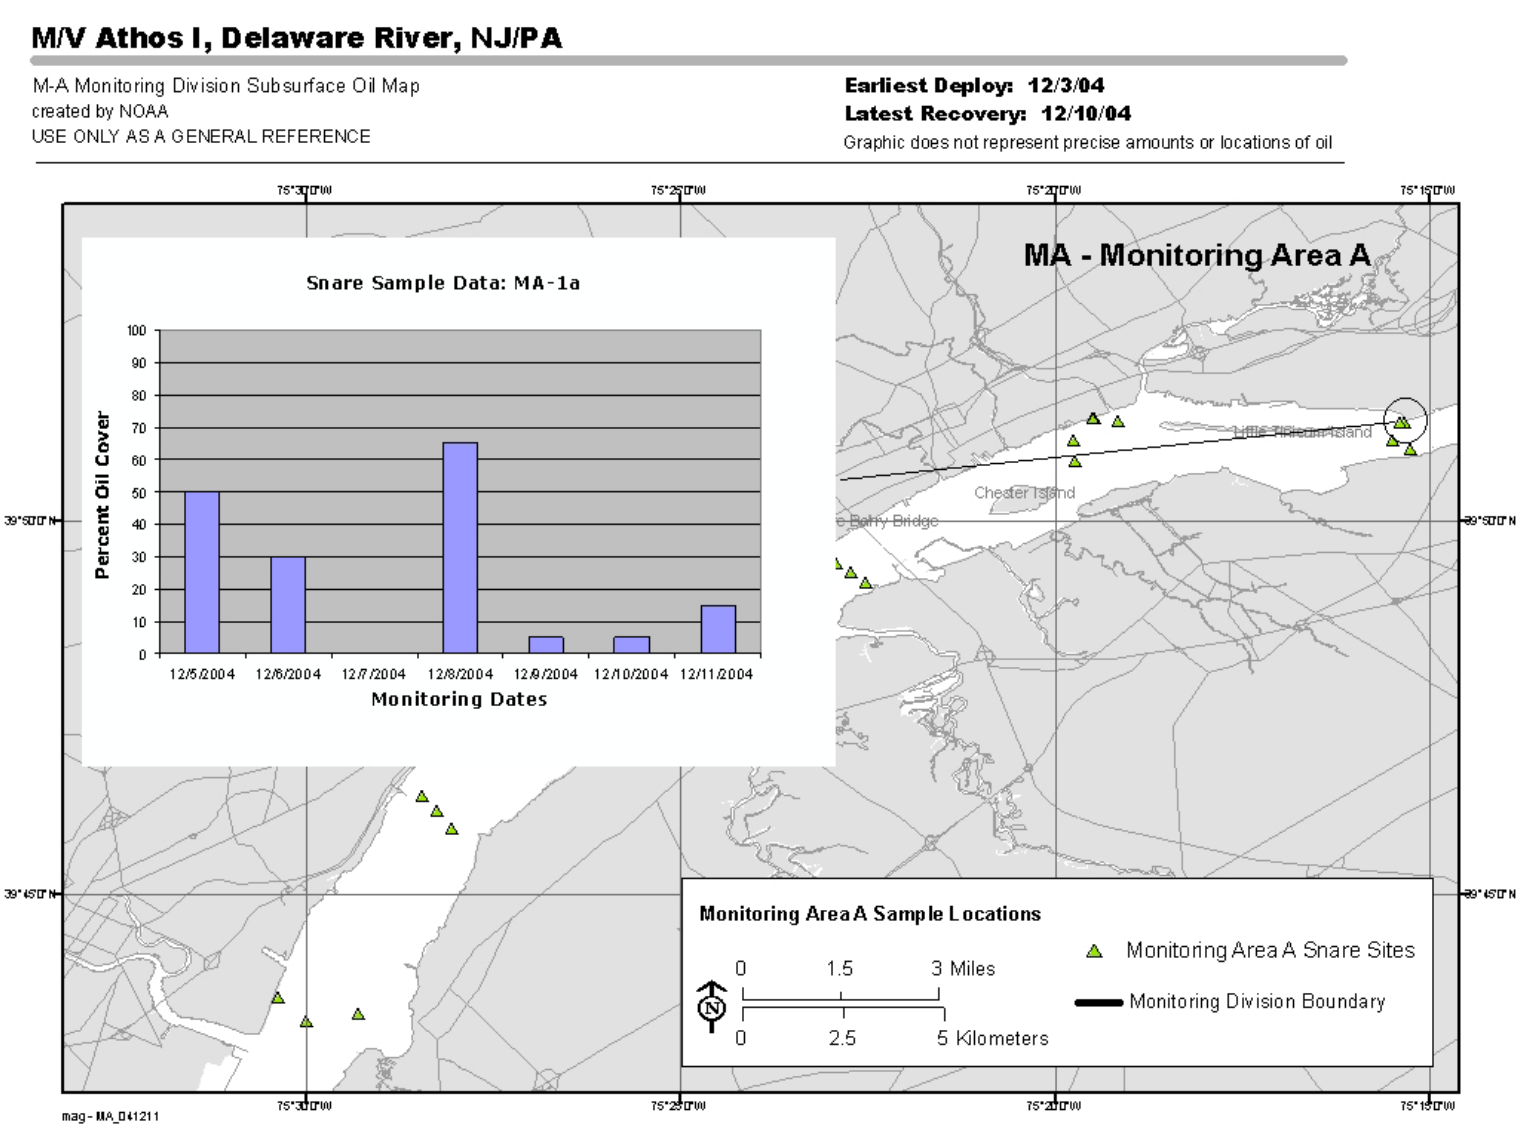

Figure 7. The oil coverage on the snare sampler just north of Tinicum Island (the location with the highest amount of oil consistently) over time. The oil coverage on 8 December represents two days of deployment, compared to the one-day deployment of the other dates. The amount of oil has been below 15% for the last three dates.

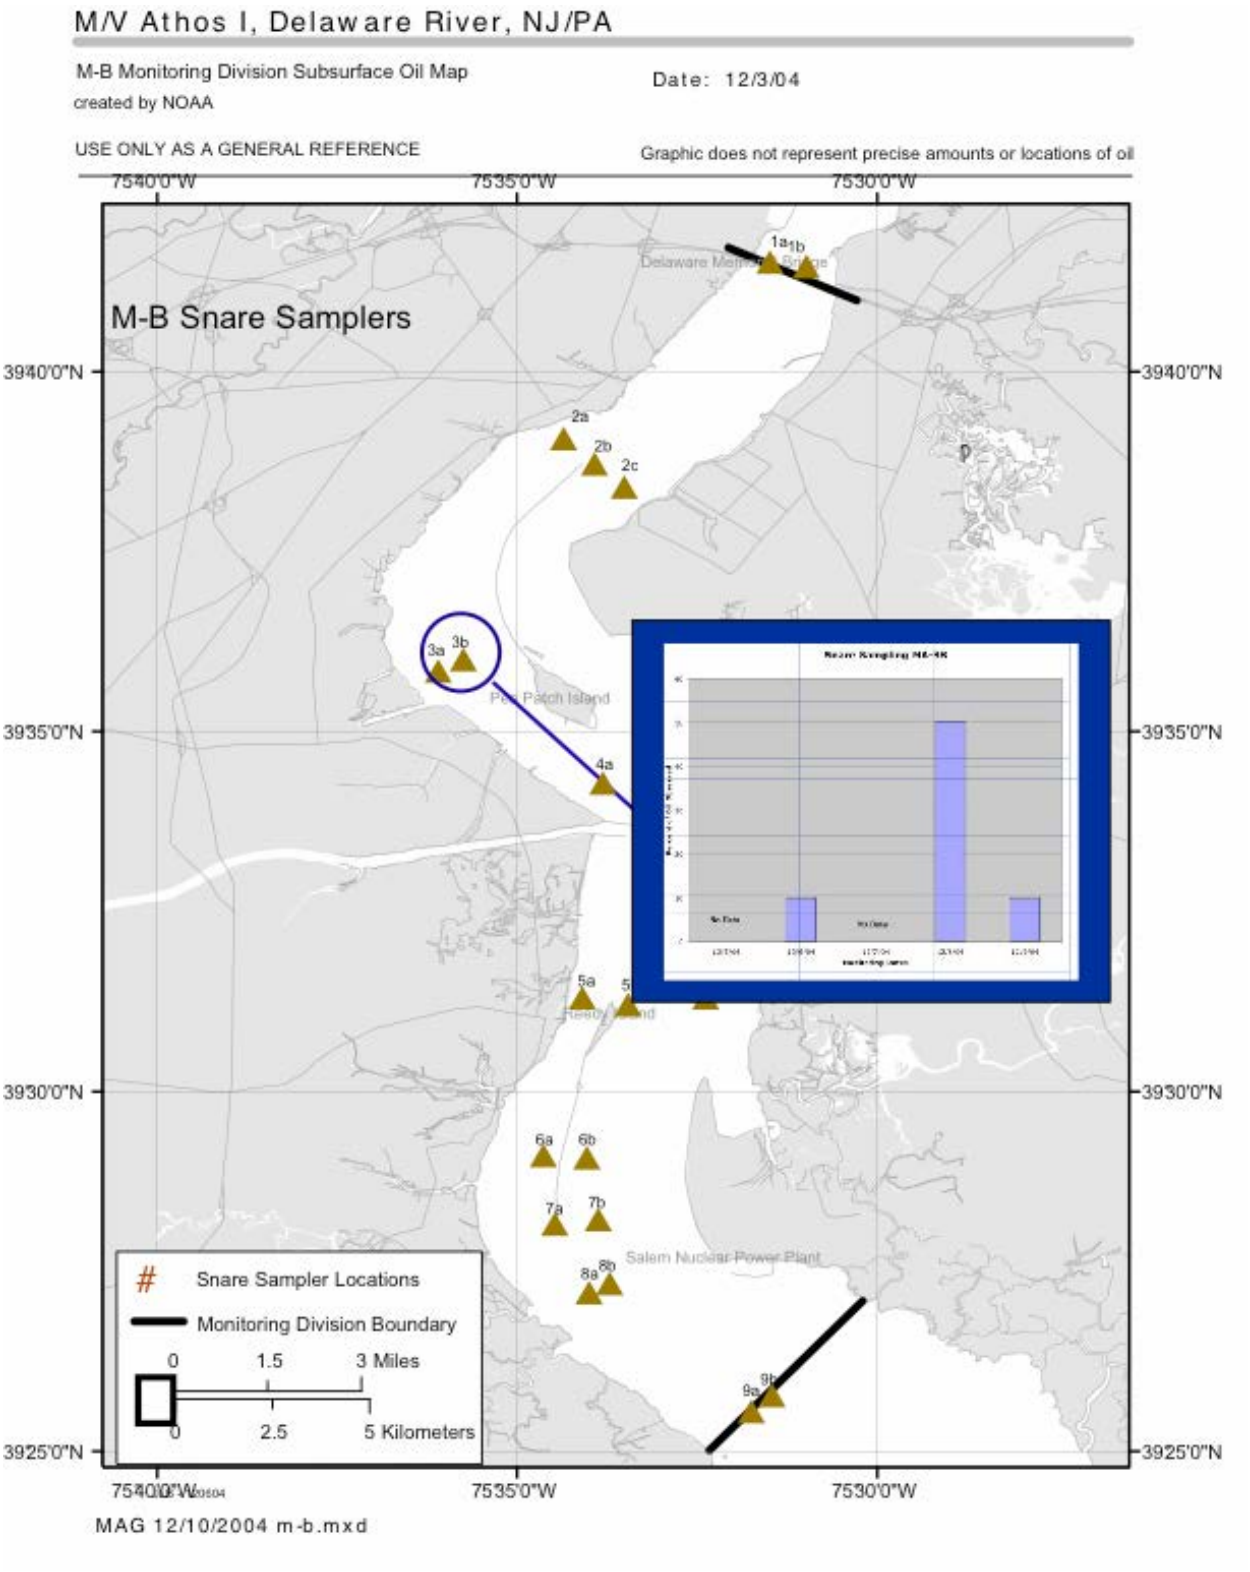

Figure 8. The oil coverage on the snare sampler west of Pea Patch Island. There was a peak on 8 December, representing two days of deployment.

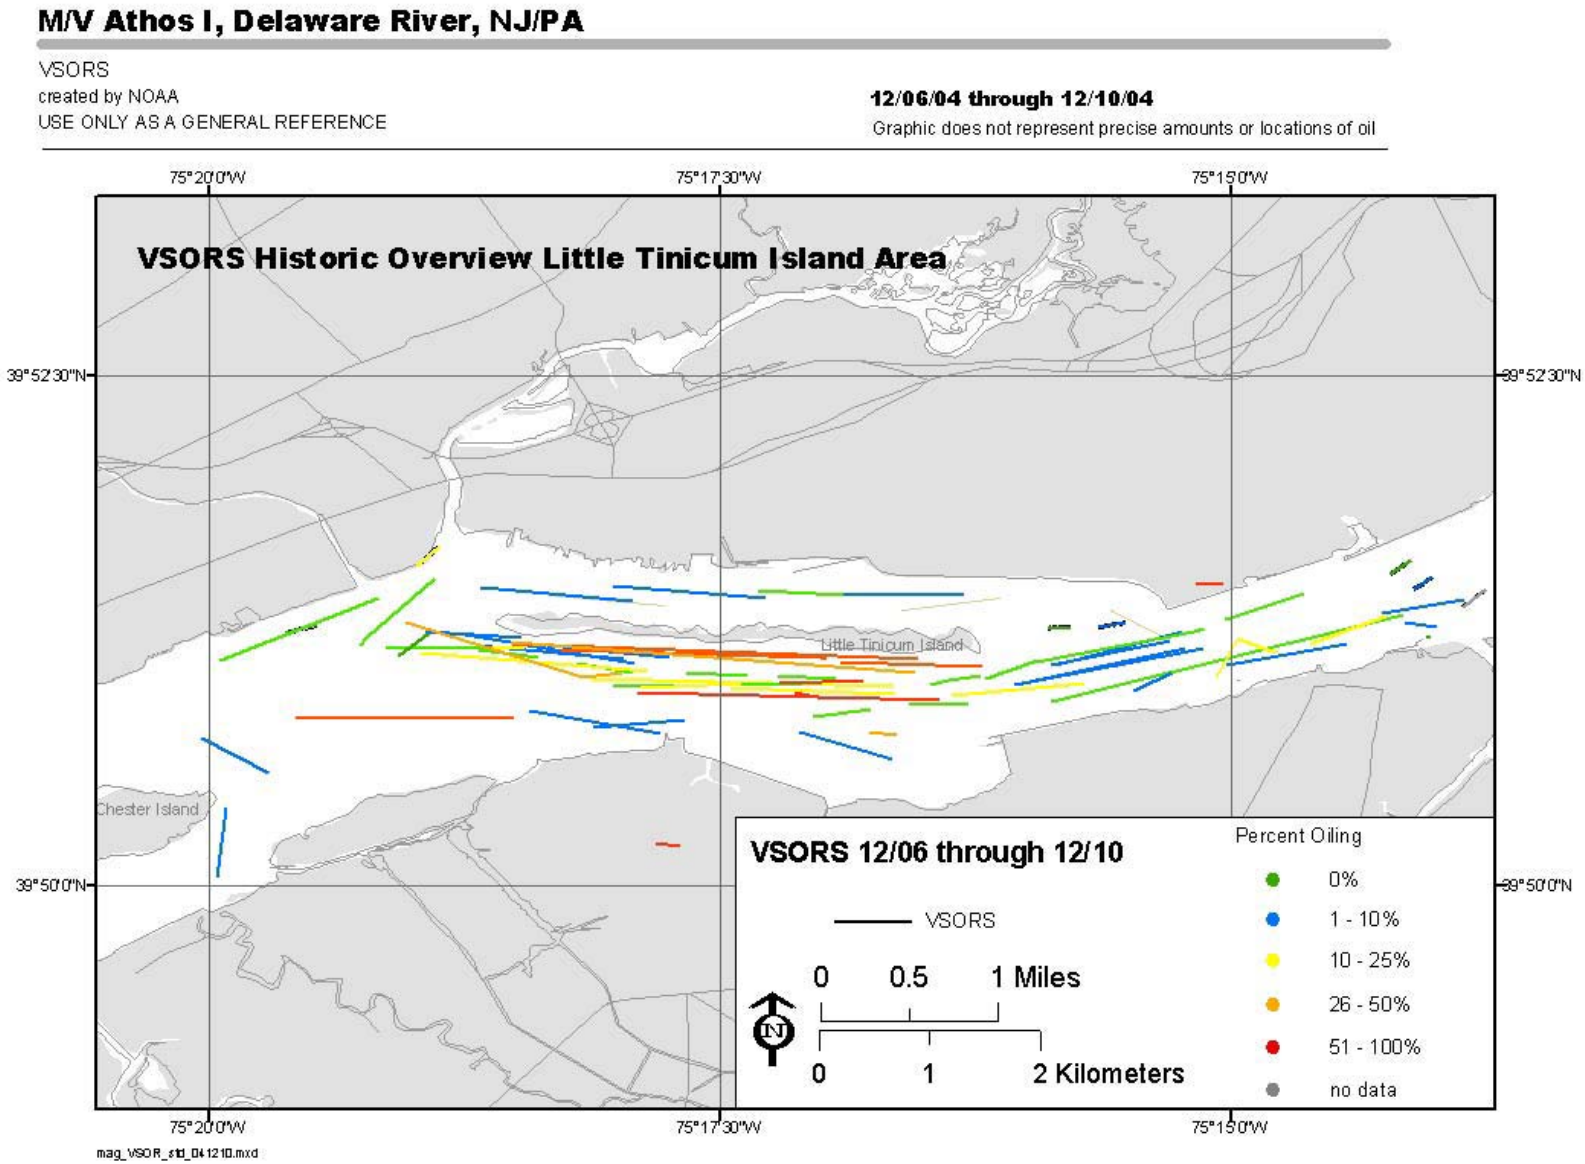

Figure 9. Track lines for the V-SORS coded according to the percent of visual oil coverage on the snares.

Additional V-SORS tows were conducted off the Salem Nuclear Power Plant on 8 December, with no oil detected. Small amounts of oil (~10%) were detected in Division MA, between the Commodore Barry Bridge and the Delaware Memorial Bridge on 8 December. Little to no oil was detected in the main shipping channel.

On 11 December, the V-SORS were directed to search for and recover oil in seventeen potential accumulation areas. Table 3 is a summary of these results. Oil was detected in the Marcus Hook Anchorage 7; a trace amount was found near Penns Grove, New Jersey (Cherry Flats).

Table 3. V-SORS results for potential submerged oil accumulation sites on 11 December 2004.

Potential Oil Accumulation Site	Percent Oil on Snares

V. SUMMARY

A significant but unknown amount of oil from the *Athos 1* oil spill did not float. The oil itself is buoyant, even after weathering, however two different mechanisms caused the oil to become submerged:

1. During the initial release, the oil was released under high pressure, cutting it's own trench in to the bottom. The highly viscous oil was held in the trench by cohesive forces. This is the only location where "pooled" oil was found.

2. The rest of the released oil initially floated and formed thick slicks. Most of the heavy oil stranded on man-made shorelines (seawalls and riprap), coating the intertidal zone. However, some thick slicks stranded on sandy shorelines (e.g., the wide intertidal sand flats on Tinicum Island) where the sticky oil picked up enough sandy sediments to make the oil slightly negatively buoyant. When this oil was eroded from the shoreline, it moved

along the bottom with the tidal currents. The mobile oil has not accumulated in significant amounts in depressions along the upper river.

The recovery of the oil in the trench will remove the only known area of pooled oil. There have been significant efforts to remove as much of the mobile oil as possible through shoreline cleanup of the re-floatable oil stranded on the intertidal zone and recovery of mobile, submerged oil using the V-SORS. Data from both the snare samplers and the V-SORS tows indicate that the amount of submerged oil has decreased over time.

Sunken Oil Detection and Recovery
Operational Guide

1 Scope

1.1 Introduction and How to Use This Guide

This Operational Guide is a companion document to the technical report, *Sunken Oil Detection and Recovery*, which identifies and documents current best practices and alternative technologies possessing the potential to more effectively detect, contain, and recover sunken oil, defined as the accumulation of bulk oil on the bottom of a water body. The technical report includes summaries and lessons learned for 36 case studies of oil spills where a significant amount of the oil sank. For each technology, it includes a detailed description of the method, advantages and disadvantages, and summary tables—the kinds of information needed to select the most effective approaches to sunken oil detection and recovery. Please refer to the technical report for supporting information not in this guide.

Most oil spill response strategies, tactics, and equipment are based on the simple principle that oil floats. However, oil does not always float. Sometimes it suspends in the water column; sometimes it sinks to the bottom of the water body. Sometimes it does all three: floats, suspends, and sinks. Furthermore, oil that has sunk to the bottom can become re-suspended and spread by currents. Terminology to describe these various behaviors can be confusing; thus, in this guide, the following terminology is used.

— **Floating oil**—Spilled oil that is on the surface of the water.

— **Submerged oil**—Spilled oil that is in the water column, below the water surface, including oil that is in temporary suspension due to turbulence and will refloat or sink in the absence of that turbulence.

— **Sunken oil**—Spilled oil that is on the bottom of the water body.

This guide addresses only sunken oil.

1.2 Section Descriptions

There are six subsequent sections to this guide.

— **Section 2: Determine the Potential for the Oil to Sink under the Spill Conditions**

This section provides guidance on when to expect that an oil may sink, either initially or later due to processes such as weathering and sediment interactions. It includes a chart to help determine if an oil can sink initially based on its density or API gravity and the salinity of the receiving water. It also includes a chart that shows how turbulence and sediment interaction can cause a floating oil to submerge or sink over time.

— **Section 3: Select Sunken Oil Detection, Delineation, and Characterization Techniques**

This section includes a checklist of the types of information you will need about the oil and spill conditions to start evaluating which sunken oil detection options may be effective for the spill. There is a list of action items to guide the development and approval of a sunken oil detection plan. It also includes tabular summaries of the advantages and limitations of possible options, along with a matrix to guide selection of the best combination of options.

It is important to note that oftentimes multiple detection, delineation, and characterization methods should be used, in combination and/or in sequence. All remote detection methods require ground truthing or need bottom sampling to determine the oil thickness on the bottom or determine the oil’s viscosity and thus pumpability.

— **Section 4: Determine if there are Feasible Sunken Oil Containment Techniques**

This section notes that containment of sunken oil may not always be feasible. It includes summaries of the advantages and limitations of possible options under mostly low-flow conditions.

— **Section 5: Select Sunken Oil Recovery Techniques**

This section includes a checklist of the types of information you will need about the oil and spill conditions to start evaluating which sunken oil recovery techniques may be effective for the spill. There is a list of action items to guide the development and approval of a sunken oil recovery plan. It also includes tabular summaries of the advantages and limitations of possible recovery techniques, along with a matrix to guide selection of the best combination of techniques.

— **Section 6: Waste Stream Management**

Because waste generation during sunken oil recovery operations is a very important consideration in both selection of the removal method and the types of waste stream treatment methods to be implemented, this section provides guidance on best practices for handling the oil, liquids, and solids generated during a response.

— **Section 7: Safety Considerations**

Safety is of paramount importance during all phases of sunken oil detection and recovery, as it is during any response. Therefore, this section includes safety considerations throughout the response. It also includes a checklist of the issues to consider when developing a plan to conduct sunken oil detection and recovery operations, including:

- general safety;
- equipment mobilization and heavy lift operations;
- hydraulic submersible pumps and transfer operations;
- diving operations.

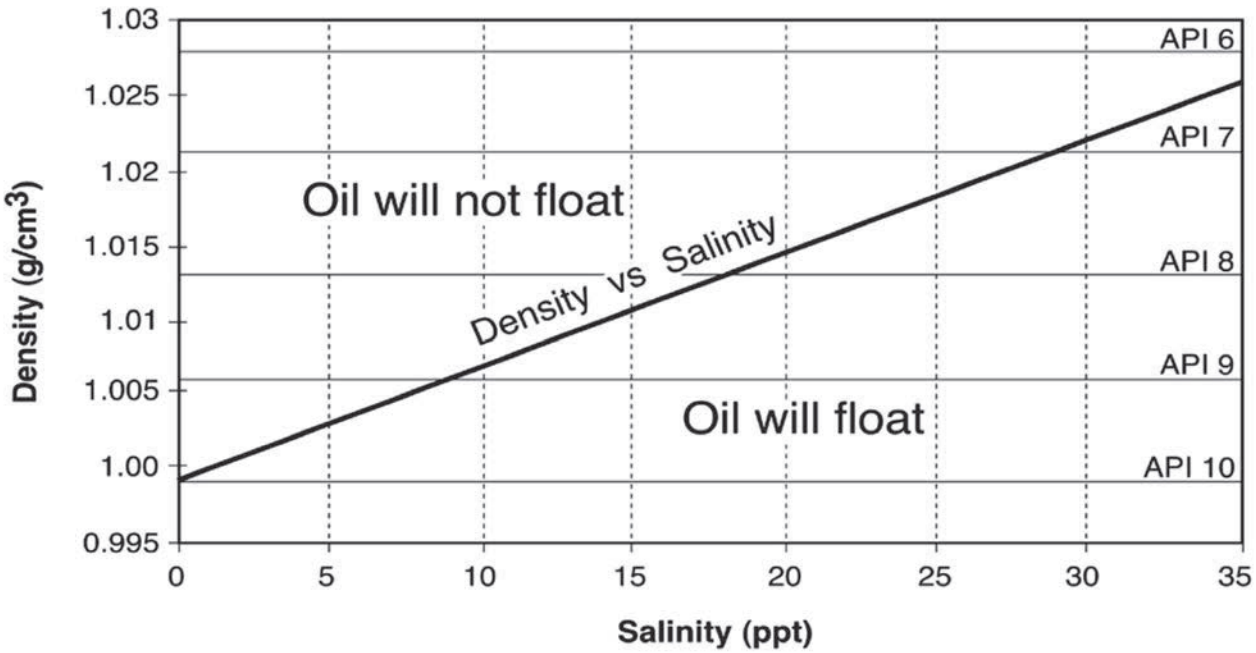
2 Determine the Potential for the Oil to Sink Under the Spill Conditions

Key points include the following.

- The API gravity or density of the oil relative to that of the receiving water will determine if the oil will sink initially after release to a water body.
- Over time, weathering or interaction with sediment can cause a floating oil to sink.
- Floating oils that may sink are generally very heavy crude oil, heavy fuel oils, or diluted bitumen products.

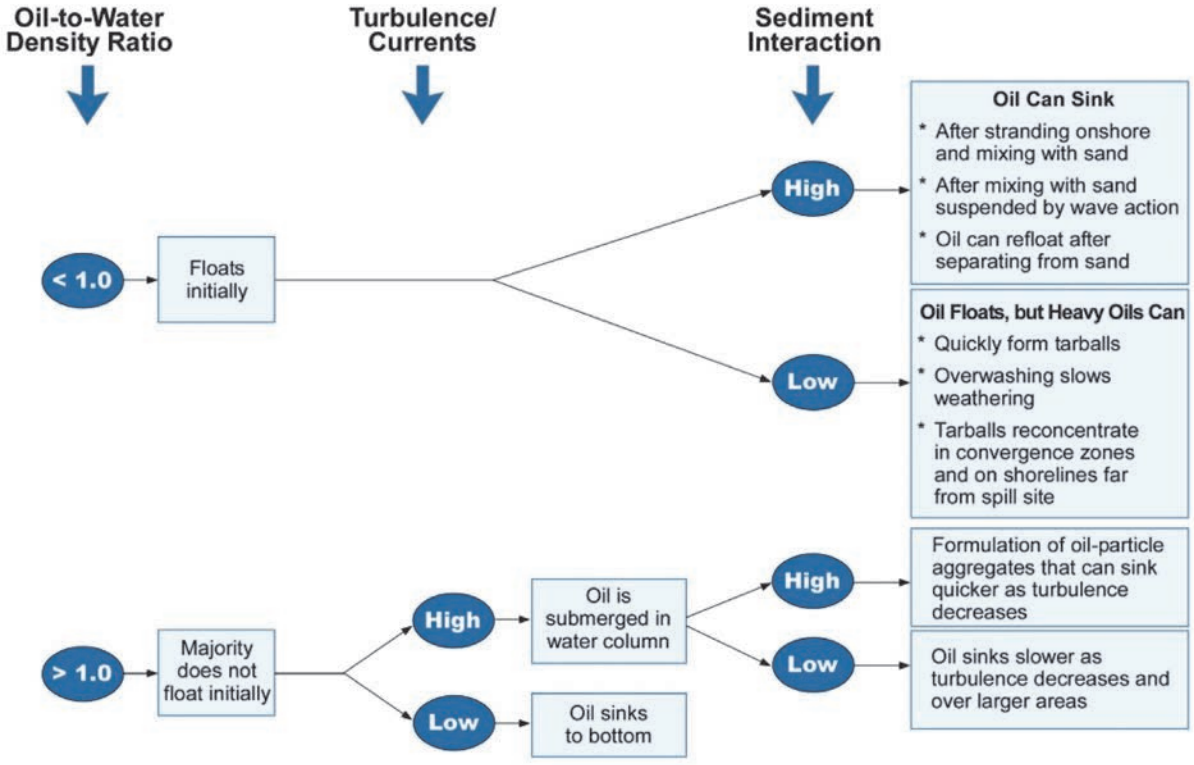
Determine the potential for the spilled oil to sink initially.

- Determine the API or density of the fresh oil and use Figure 1 and Figure 2 to determine if it will sink initially in the receiving water.
- In freshwater, oils with an API of less than 10 or a density of greater than 1.0 g/cm^3 will sink if the currents are weak or turbulence is low.



NOTE Oils with values below the line will float initially; oils with values above the line with not float initially (modified after NRC, 1999).

Figure 1—Relationship Between Density and API Gravity and Water Salinity



NOTE Modified after NRC, 1999.

Figure 2—Conditions by Which Oils Can Sink Based on the Density of the Oil Relative to the Receiving Water, Turbulence, Currents, and Sediment Interaction

— In seawater, oils with an API of less than ~6.5 or a density of greater than 1.03 g/cm^3 will sink if the currents are weak or the turbulence is low.

— In estuarine waters, be aware that the oil might be suspended in the water column in the freshwater part of the estuary or river, then refloat once it reaches the higher salinity water closer to the mouth of the estuary.

— Conversely, oil that floats or is submerged in estuarine waters may become submerged or sink if transported into less dense freshwater.

— If the currents or turbulence are strong, oils heavier than the receiving water will become suspended in the water column and only sink in low-flow areas downcurrent of the release. These low-flow and low-energy areas should be targets for searching for sunken oil.

Determine the potential for the spilled oil to sink over time.

— Experience has shown that oils that initially float can sink after mixing with sediment. This can occur by two pathways.

  — Floating oil that mixes with sediment after being stranded on a beach can be reworked and moved seaward by wave action to sink in the adjacent nearshore waters.

  — Floating oil can mix with sand in the surf zone and sink, without ever stranding onshore.

— Some oils are lighter than water initially but become close to or even heavier than the density of freshwater once the lighter fractions are lost by evaporation. These oils can sink as either bulk oil or oil-particle aggregates on the bottom of the water body.

— Highly viscous oils can have an increased risk of sinking over time.

  — They can entrain a lot of free water, which can increase their density.

  — They tend to be stickier, which can increase the amount of sediment uptake if stranded on the shoreline or mixed with sediments in the water column, which can increase their density.

3 Select Sunken Oil Detection, Delineation, and Characterization Techniques

Key points include the following.

— Stand up a Sunken Oil Detection, Delineation, and Characterization Group responsible for methods evaluation as soon as it is determined that there is a risk of oil sinking.

— Start mobilizing equipment as soon as possible.

— Recovery should be closely coupled with detection because sunken oil can quickly become remobilized, reducing the overall effectiveness of the response. Thus, evaluation of recovery methods should start as soon as it is confirmed that the oil may sink.

— Include equipment redundancy and alternatives to the preferred method(s) in the plan because of frequent breakdowns, changing conditions, and uncertainty in which methods are likely to be most successful.

— Refer to the matrices in Table 1 and Table 2 on the advantages and disadvantages of sunken oil detection, delineation, and characterization options and the summaries in Table 3 to guide selection of the best options for the spill conditions.

Table 2—Advantages and Disadvantages of Sunken Oil Detection, Delineation, and Characterization Technologies

Advantages	Disadvantages
Side Scan Sonar >350 kHz	
— Rapid area coverage. — Good bottom oil detection shown in T/B *Apex 3508* and T/B *DBL-152* spills. — Able to detect oil patch as small as 1 m^2.	— Requires ground-truth for absolute validation of sonar data. — Will not be able to detect buried oil.
Multibeam Echo Sounder >350 kHz	
— Easy to deploy and provides pseudo-imagery of the bottom. — Provides bathymetry maps showing low spots where sunken oil could collect. — Bathy data may be needed to support recovery Ops.	— Resolution is lower than side scan sonar making interpretation/detection of oil difficult.
Sub-bottom Profiler 4 to 24 kHz Chirp	
— Provides potential for detection of oil mats in the shallow sub bottom region when used in conjunction with side scan sonar and multibeam echo sounders.	— Cannot detect sunken oil on the surface. — Data are difficult to interpret due to limitation in resolution of layering in the sub bottom region.
3D Scanning Sonar	
— 3D mapping and tracking of submerged or subsurface oil. — Real-time observation of sunken oil on the bottom for recovery operations.	— Limited availability in the commercial offshore market.
Digital Still Camera	
— Very high resolution images.	— Discrete images do not provide continuous images of the bottom. — Water turbidity limits effectiveness.
Video Camera	
— Provides continuous color or b/w images of the bottom. — Low-light b/w cameras facilitate imaging in high turbidity conditions by eliminating requirement for light sources.	— Water turbidity limits effectiveness for imaging.
SPI Camera	
— Provides digital images of near sub-bottom for identification of sunken or buried oil layers and benthic communities.	— Fouling of SPI window due to oil in water column or sunken oil on the bottom.
Acoustic Camera	
— Provides acoustic imaging in very high turbidity water conditions. — Could be deployed at a site to monitor sunken oil behavior over time or during events such as storms.	— Acoustic images have limited resolution when compared to optical images.

Table 2—Advantages and Disadvantages of Sunken Oil Detection, Delineation, and Characterization Technologies (Continued)

Advantages	Disadvantages
Diver Observations	
— Proven effective in detecting, mapping, and recovering sunken oil. — Quick turnaround on data; divers provide real-time imagery to the surface, may be directed by the diving supervisor and technical specialists while on the bottom, and can immediately communicate observations to the surface. — Often effective in low to no visibility conditions; divers can feel the oil and changes in bottom topography. — Accurate determination of oil on bottom; can provide verbal and visual description of extent and thickness of oil and spatial variations. — Experienced river divers can conduct detection and recovery operations in high current environments that typically restrict ROV operations or towed systems due to bottom obstructions. — Submersibles and one-atmosphere diving suits may be used to increase depths and bottom times. — Low false positives.	— Environmental limitations may include sea state, currents, weather/lightening, water depth, ice/cold water, debris, and dangerous marine life. — Surface-supplied air diving is limited to 190 feet of salt water (fsw) in the US. Mixed gas, saturation systems, and one-atmosphere suits or submersibles may increase bottom time and depth; will increase project complexity and cost. — Coverage rate; the length of the diver's umbilical limits movement away from the dive support vessel. — Contaminated water diving requires special equipment, training, and decon procedures. — Diving in high-current rivers and ice/cold water requires special training, additional equipment (such as hot water suits and dry suits), and experienced divers. — Slow; diver movements may be limited by umbilical length and environmental conditions. — Divers must be replaced routinely to remain within no-decompression limitations and work/rest standards.
Towed Sorbents (Heavy)—Sorbents attached to multiple chains attached to a header bar	
— Can be towed at up to 5 knots, though usually 3 to 4 knots, thus able to cover a large distance. — Area swept is about 8 ft. — Higher confidence that it maintains bottom contact. — Can vary the length of the trawl to refine spatial extent, to some degree. — Good positioning capability with onboard GPS; can load assigned tracks into the vessel navigation system. — Can be used in vessel traffic lanes.	— Requires larger vessel with crane or A-frame and winch to deploy/retrieve. — Lots of concern about pipeline and debris snagging. — Cannot determine where along the trawl the oil occurred; No calibration with actual amount of oil on bottom. — Longer transects because of handling difficulty. — Highly dependent on wave conditions.
Towed Sorbents (Light)—Sorbents attached to a single chain	
— Manually deployed so can be used on smaller boats. — Can have very short trawls, if needed. — Can conduct continuous surveys without stopping, towed at 2 to 3 knots.	— Narrow swath (~1 ft) so less information on patchy oil. — Concerns about it losing contact with the bottom with wave action. — Cannot determine where along the trawl the oil occurred. — No calibration with actual amount of oil on bottom. — Highly dependent on wave conditions.

Table 2—Advantages and Disadvantages of Sunken Oil Detection, Delineation, and Characterization Technologies (Continued)

Advantages	Disadvantages
Stationary Sorbents—Detection of oil in the water column or along the bottom	
— Proven to be effective at detecting oil at various depths in the water column and moving along the bottom. — Time-series data very useful to track trends, though requires a lot of data points to be meaningful. — Can be re-deployed as needed as the oil migrates down current.	— Time and labor intensive for deployment, inspection, and replacement. — Can have high loss rates. — No calibration of the efficacy of oil adsorption and it might change over time. — Can not be deployed in active vessel traffic lanes. — Low temporal data on when the oil was mobilized.
Visual Observations by Trained Observers	
— Aerial surveys can cover large areas quickly. — Data are collected in real time, rather than having to view video post-collection. — Observers can adjust their survey once sunken oil is located for better detail. — During water surface surveys, it is possible to stop to take samples to confirm an observation as oil and take photographs.	— Only effective in clear, shallow water during daylight hours. — Not effective for buried oil. — Aerial observations will only identify general areas for ground truthing and more detailed assessment. — Aerial observations are not effective for small, patchy accumulations. — Water surface observations collect data along narrow transects so of limited spatial detail. — Even trained observers can make false positive or negative observations.
Bottom Sampling	
— Allows collection of samples to confirm the presence of oil, either visually or through chemical analysis. — Can be effective in small areas for rapid delineation of a known patch of oil. — Poling method indicated the relative risk of sheening of sunken oil. — Can detect buried oil and indicate oil thickness.	— Only point sample of a very small area. — Not effective in patchy oiling conditions. — Very slow and labor intensive. — Even slower in deep water, rough sea conditions. — Oil may be buried deeper than the sampler can penetrate into the bottom. — Must use a statistically relevant sampling grid to be useful.
Laser Fluorosensors	
— Highly sensitive to oil. — Generates few false positives once calibrated for the sunken oil. — Can be used during day or night.	— Cannot detect buried oil. — Detection ability decreases with water turbidity, distance from the target, and wave height. — Bright, backscattered light (such as from white sand) may saturate the input. — Only one prototype system available, and the latest model has not been tested.

Table 2—Advantages and Disadvantages of Sunken Oil Detection, Delineation, and Characterization Technologies (Continued)

Advantages	Disadvantages
Water Column Sampling	
— Can provide geo-referenced oil locations in real time and at high spatial resolution. — Once oil is detected, the survey can be adapted to sample above potential targets. — Mass spectrometers can determine hydrocarbon composition, allowing differentiation among sources. — Can map gradients of oil levels in the water column, which could be used to identify areas of higher oil accumulations. — Submersible UV fluorometers are readily available and easily deployed and interpreted. — Submersible mass spectrometer technology and availability are improving. — Other sensors can be added to the vehicle to measure other parameters, e.g. salinity, dissolved oxygen, temperature.	— Only works if there are soluble components or small oil droplets in the water column. — The rate of release of soluble oil may decrease to non-detectable levels quickly. — Submersible mass spectrometers require a specially trained team of operators and interpreters.

Table 3—Summary of Sunken Oil Detection Technologies

	Sonar Systems	Still, Video, and Acoustic Cameras	Diver Observations
Description	Sonar systems are utilized to detect sunken oil on the bottom and in the near sub bottom areas.	Visualization devices including still, video and acoustic cameras are utilized to validate the presence of sunken oil.	Professional commercial divers trained, experienced, and equipped for contaminated water diving operations.
Logistical Needs	Support vessels of sufficient size and sea-keeping capability are required to provide an operational platform for the sonar systems. Different sonar systems have specific platform requirements so care must be taken in platform selection to ensure compatibility.	Visualization systems have definite platform requirements depending on technique selected. Diver-operated video devices have specific diver-related logistic requirements as noted for Diver Observations, which must be adhered to.	Diving support vessel/platform; heavy-lift equipment to load compressors, dive control rooms, and other equipment onboard. Emergency transportation to a medical facility with a multi-place decompression chamber. Decompression chamber located on-site as a contingency.
Operational Limitations	Water depth of 10 ft or less establishes an operation limitation on acoustic techniques, although operations in shallower water are possible in certain situations.	Water turbidity limits the functionality of visualization devices with the exception of the acoustic camera which will function in zero visibility water conditions with lesser resolution than optical devices.	Surface-supplied air diving is restricted to 190 fsw. Diving operations are limited by depth, bottom time, visibility, currents, and other environmental conditions.
Pros	Sonar systems are easy to use and have a high area coverage rate for fast establishment of sunken oil locations on the bottom.	Visualization techniques and devices provide visual validation of the presence of sunken oil without the requirement for ground truth of images.	Accurate, immediate observations can be conveyed to the surface. If visibility permits, real-time video can be viewed in the dive control house.

Table 3—Summary of Sunken Oil Detection Technologies (Continued)

	Sonar Systems	Still, Video, and Acoustic Cameras	Diver Observations
Cons	For absolute detection, sonar systems require a ground truth of the detected contact on the bottom to provide positive identification of sunken oil.	Water turbidity limits the capability of visualization devices with increasing turbidity creating decreasing visibility until the acoustic camera is required which provides images of lesser resolution than optical techniques.	Diving in contaminated water is considered a “high-risk” operation requiring thorough planning, safety oversight, trained and equipped personnel, and specialized equipment. The operational limitations noted above combined with diver decontamination requirements often result in a relatively high cost and time-consuming operation.
	Towed Sorbents	**Stationary Sorbents**	**Visual Observations by Trained Observers**
Description	Snares attached to chains are dragged on the bottom at set intervals then pulled up for observation of oiling amount.	Sorbents are suspended in the water column and/or placed in pots/cages on the bottom and inspected at set intervals.	Observers visually detect and record oil on the bottom as seen from aircraft or boats.
Logistical Needs	Light tows (1 chain) can be deployed on small boats. Heavy tows (multiple chains with a header bar) require a vessel with a crane or A-frame and pulley to deploy/ retrieve the tows.	In shallow water, requires minimal support. In deep water, requires davits or winches to deploy and retrieve them.	Aircraft or boat; GPS units to record locations and geo-reference photos; field computers to record descriptions.
Operational Limitations	Standard safety limits for boat operations. No use possible in the surf zone or where snagging on the bottom is of concern. More difficult to deploy/retrieve in >100 ft water depths.	Standard safety limits for boat operations. No use possible in the surf zone or vessel traffic lanes. More difficult to deploy/retrieve in >100 ft water depths.	Can only be used during daylight periods. Standard safety limits for aerial and boat operations, including no surveys possible in the surf zone.
Pros	Effective in low visibility conditions; can be used in vessel traffic lanes; can vary the tow length to refine spatial extent; can be used to confirm removal.	Proven effective at detection of oil moving at various depths in the water column; time-series data are useful to track trends; can be re-deployed as the oil migrates down current.	Aerial surveys can cover large areas quickly and can be adjusted once oil is found to get more detail.
Cons	Do not know where along the tow the oil occurred or how much oil is present (one larger patch or lots of small patches); cannot determine duration of bottom contact or efficacy of oil adhesion; labor intensive.	Very time and labor intensive; can have high loss rates, no calibration of the efficacy of oil adsorption and changes over time; cannot be deployed in active vessel traffic lanes; low temporal data on when the oil was mobilized during the deployment.	Cannot detect buried oil; effective only in clear water and daylight; aerial surveys require ground truth; boat surveys are slow; not safe for work in surf zone, strong currents.

Table 3—Summary of Sunken Oil Detection Technologies (Continued)

	Grab or Core Sampler	Wading-Depth Manual Shovel Pits	Laser Fluorosensors	Water-Column Sampling
Description	Point locations are surveyed with sediment grabs or cores to bring a sample to the surface for description.	A narrow blade shovel is used to dig shallow pits underwater, bringing the sediments to the surface for oil description.	Laser is used to excite the aromatic compounds in the oil to emit light with a unique pattern.	Underwater unit (fluorometer and/or mass spectrometer [MS]) is towed above the bottom to detect oil dissolved/ dispersed in the water.
Logistical Needs	In shallow water, requires minimal support. In deep water, requires a winch, A-frame, etc.	Can require a large team, depending on safety issues and access. Requires safety boat/crew at site, boats for access to sites with no land access.	Unit must be towed close to the bottom; could be deployed on ROV as well.	Units are deployed from boats; navigation system used to record location and measurements in 3D.
Operational Limitations	Standard safety limits for boat operations. No surveys possible in the surf zone.	Many safety limits. Requires wading water depth, low waves and currents, light wind, no lightning, and warm water.	Detection decreases with water turbidity, distance from the target, and wave height. Bright light can interfere. Water depths accessible by boat.	Standard safety limits for boat operations. No surveys possible in the surf zone. Water currents must be low enough to minimize transport of the plume.
Pros	Samples can be collected for confirmation; can detect buried oil and oil thickness; poling can indicate the risk of sheen generation.	May be best option to detect buried oil in the surf zone; can work closely with Operations to achieve rapid removal after delineation of treatment area.	Highly sensitive, few false positives; can be used day or night.	Can map at high spatial resolution and differentiate among oil sources in real time, allowing detailed mapping of targets.
Cons	Slow, labor intensive, not effective for patchy oil; weather and sea limits.	Narrow operational limits, slow coverage rate, and limited to depth of digging.	Cannot detect buried oil; not effective in turbid water; not proven operationally.	Only effective if there is oil in the water; currents can transport the oil away from source; MS requires special teams and gear.

The following is a checklist of actions and information needs for the Sunken Oil Detection Group.

Site Characteristics

- ❑ Survey area (highest priority, next priority): _____
- ❑ Distance from shore: _____
- ❑ Water depth range: _____
- ❑ Water visibility range: _____
- ❑ Water current speed and direction:

  Surface: _____

  Subsurface: _____
- ❑ Wave conditions: _____
- ❑ Substrate type: _____
- ❑ Bathymetry (oil accumulation areas): _____
- ❑ Sensitive habitats in survey area: _____

  Biological resources: _____

  _____

  Cultural/historic resources: _____

  _____
- ❑ Types of obstructions on the bottom: _____
- ❑ Other restrictions to be considered: _____
- ❑ Landowner issues: _____

Evaluate/select the best detection techniques.

1) Select possible detection techniques based on water depth.

2) For the selected techniques, filter them based on water turbidity.

3) Factor in substrate type, presence of bottom obstructions, patch size, whether there is sensitive habitat, and potential for false positives.

4) Refer to the technical report for coverage rates for different sonar systems to estimate the number of days needed to complete the survey.

5) Determine availability and mobilization time. Remember, experienced operators will greatly improve the effectiveness and timeliness of the results.

6) Involve potential qualified contractors in the planning process as they can provide valuable feedback on applications of various techniques. In discussions with potential qualified contractors, provide the site characteristics listed above. Be clear about expected turnaround time, deliverables, and what logistics will be provided.

7) The Sunken Oil Detection Group reviews the detection techniques that are most likely to be effective for the spill conditions and the qualifications of potential contractors to provide the equipment and trained operators.

8) Results of the review are documented in a draft Sunken Oil Detection Plan that is submitted to the Environmental Unit for review and compliance with federal and state permitting and consultation requirements, including:

   a) Section 7 of the Endangered Species Act (ESA),

   b) Essential Fish Habitat (EFH) under the Magnuson Stevens Fisheries Conservation and Management Act,

   c) Section 106 of the National Historic Preservation Act (NHPA),

   d) State Historic Preservation Office,

   e) federally recognized Native American Tribal Governments.

9) After review by the Environmental Unit and with appropriate changes, the Planning Section Chief submits the final Sunken Oil Detection Plan to the Unified Command for review and approval.

10) Once the Unified Command has approved the plan, prepare a ICS 213 resource request form and route through Finance and Logistics for approval and notification of the selected contractor(s).

11) Once approved, contact the contractors to start the planning for the survey.

4 Determine Whether There Are Feasible Sunken Oil Containment Techniques

Oil usually accumulates on the bottom where currents and turbulence are low. However, sunken oil can be remobilized when turbulence increases, such as during higher-flow conditions in rivers and higher-wave conditions in nearshore areas. Containment of sunken oil may not always be feasible. If containment is being considered, use the information on site conditions in Section 3 to determine if there are feasible techniques to contain the oil under the spill conditions. Only those sunken oil containment techniques that have shown to be effective are listed in Table 4.

5 Select Sunken Oil Recovery Techniques

Key points include the following.

— Stand up a Sunken Oil Recovery Group responsible for methods evaluation as soon as it is determined that there is a risk of oil sinking.

— Start mobilizing equipment as soon as possible.

— Safety of the responders and public should remain the top priority throughout the recovery operation (reference Section 7 of this guide).

Table 4—Advantages and Disadvantages of Sunken Oil Containment Technologies

Advantages	Disadvantages
Filter Fences or Gabion Baskets Filled with Sorbents	
— Constructed of readily available materials. — Effective at removal of oil droplets in the water column. — Can be deployed at and just below the surface or on the bottom, depending on water depth and where the oil is moving in the water column or along the bottom. — Closed-loop snare may be more effective.	— If currents are >1 ft/s, there can be scouring of the bottom in front of the baskets and less effective oil recovery. — Not feasible to deploy in high-flow areas. — Can completely fail and be swept downstream if flows suddenly increase. — Can only filter the entire water flow in small streams.
Sediment Curtains	
— Curtains constructed of hydrophilic materials can sorb oil as well as slow the flow and increase sedimentation. — Half-curtains or partial currents can be deployed at angles to the flow in moderate-flow areas to slow currents and increase deposition of oiled sediments.	— Full curtains are only effective in low-flow areas, where the curtain can maintain contact with the bottom, where risk of oil mobilization is also low. — Requires measurement of current speeds at surface and/or bottom and knowledge of hydraulics for proper design. — -Can interfere with navigation.
Air Curtains	
— Does not interfere with navigation. — Could help bring oil in the water column to the surface.	— Only effective in very low-flow areas, where risk of oil mobilization is also low.
Enhanced Passive Sediment Accumulation	
— Builds on natural processes and uses natural materials that can be left in place. — Does not interfere with navigation.	— Restricted to areas of natural accumulation, which may be sensitive or high-public use areas such as impoundments. — Requires dredging or excavation to remove the accumulated sediment. — Need a good understanding of seasonal flow patterns so sudden floods don’t flush the oiled sediments out.

— Recovery should be closely coupled with detection because sunken oil can quickly become remobilized, reducing the overall effectiveness of the response. Thus, start evaluation of recovery methods as soon as it is confirmed that the oil may sink.

— Include equipment redundancy and alternatives to the preferred method(s) in the plan because of frequent breakdowns, changing conditions, and uncertainty in which methods are likely to be most successful.

— Develop and get consensus on cleanup endpoints, which will greatly influence selection of removal techniques and validation methods.

— Refer to the matrices in Table 5 and Table 6 on the advantages and disadvantages of sunken oil recovery techniques; and see Table 7 to guide selection of the best techniques for the spill conditions.

The following is a checklist of actions for the Sunken Oil Recovery Group.

Table 6—Advantages and Disadvantages of Sunken Oil Recovery Technologies

Advantages	Disadvantages
Suction Dredge with Cutter/Auger Head Attachment	
— Common piece of equipment, readily available, easy to transport. — Little to no modifications required for sunken oil recovery. — Can cover large areas quickly with 5 ft to 8 ft swath. — Ability to pump/transport great distances. — Ability to pass large solids, i.e. rocks and debris. — Self-propelled or guide-cable operation. — Adjustable “cut” depth allowing the removal of ±1 in. to several inches in one pass. — Can track and document progress with GPS. — Low manpower requirement to operate. — Amphibious models can operate from 0 ft to 20 ft for small units and up to 40 ft for large units.	— Generates large amounts of water and sediment requiring dewatering, handling of solids, and water treatment. — Only suitable for protected waters. — Non-discriminate recovery, cannot tell the difference between oil and water/sediment. — High rpm pump has the potential to create issues with turbulence that results in oil emulsification and shearing. — Not allowed to work in areas with pipelines, cables, or other obstructions.
Diver-directed Vacuuming	
— Vacuum trucks readily available. — Portable Vacuum Transfer Units (VTUs), while not as prolific as vacuum trucks, are available. — Ability to regulate flow. — Minimal mixing of recovered fluids and solids. — Ability to pass some solids (rocks and debris). — Can handle high viscosity. — Selective recovery provided diver has visibility.	— Rapid loss of effectiveness due to hose distance. — Large, heavy units. — Requires larger vessel or barge if unprotected water. — Small coverage area.
Diver-directed Pumping with Centrifugal Pump	
— Lightweight and portable. — Can pump long distances. — High head pressure, can pump several hundred feet up. — Easily modified to protect from rocks with a “rock box”. — Ability to regulate flow. — Selective recovery provided diver has visibility. — Can introduce steam or hot water to reduce viscosity. — Ability to pass some solids (rocks and debris).	— Not readily available; must locate from dive or dredge contractors, some oil spill response organizations. — Generates large amounts of water and sediment requiring dewatering, handling of solids and water treatment. — High rpm pump has the potential to create issues with turbulence, emulsification, and shearing. — Cannot handle viscous oil other than small amounts moved in large amounts of water. — Small coverage area.

Table 6—Advantages and Disadvantages of Sunken Oil Recovery Technologies (Continued)

Advantages	Disadvantages
Diver-Directed Pumping with Positive-displacement Pump	
— Lightweight and portable. — Can pump long distances. — High head pressure, can pump 100s of feet up. — Easily modified to protect from rocks with rock box. — Ability to regulate flow. — Selective recovery provided diver has visibility. — Can handle very high viscosity oils; can introduce steam or hot water to reduce viscosity. — Ability to pass some solids (rocks and debris). — Low rpm thus minimal mixing of fluids and solids, reducing the potential issues associated with turbulence, emulsification, and shearing. — Can adapt water-injection flange for viscous oil.	— Not readily available; must locate from dive or dredge contractors, some oil spill response organizations. — Lower recovery rates than centrifugal pumps. — Small coverage area.
Excavator	
— Readily available in varying sizes. — Can work from shore for nearshore work. — Can work from vessel or barge. — Amphibious models available but less prevalent. — Can scoop sunken oil with bucket. — Easy addition of a thumb attachment for recovering solid or semi-solid sunken oil. — No issues with rocks or debris. — Can track progress with geo-referenced data.	— Limited to ±20 ft of water. — Difficult to be selective, resulting in additional sediments. — Difficult to manage liquid flowing from bucket during lift. — Large, heavy units. — Requires larger vessel or barge if unprotected water. — Small coverage area.
Grab or Clamshell Dredge	
— Readily available from dredge and construction contractors. — Can work from shore for nearshore work. — Can work from vessel or barge. — No issues with rocks or debris. — Can track progress with geo-referenced data.	— Requires logistical support to store and transport recovered sunken oil and sediment (hopper barge). — Generates large amounts of sediment requiring dewatering, handling of solids, and water treatment. — Liquids not contained, allowing leakage during recovery operation. — Small coverage area.

Table 6—Advantages and Disadvantages of Sunken Oil Recovery Technologies (Continued)

Advantages	Disadvantages
Environmental Clamshell Dredge	
— Available from dredge, construction and environmental engineering contractors. — Can work from shore for nearshore work. — Can work from vessel or barge. — No issues with rocks or debris. — Water-tight seal greatly reduces liquid leakage. — Can track progress with geo-referenced data.	— Not as prevalent as conventional clamshell. — Small coverage area.
Sorbents/V-SORS	
— Can be used in active vessel traffic lanes. — Track lines can be recorded with the vessel's GPS to provide actual survey lines. — Could detect both pooled and mobile oil moving above the bottom, but won't differentiate between them. — Relatively efficient in that large areas could be surveyed. — Readily available; can be sized for the task. — Low tech; easy to train crews. — Can vary the length of the trawl to refine spatial extent.	— Time and labor intensive for deployment, inspection, and replacement. — Susceptible to snagging on the bottom. — Cannot determine where along the trawl the oil occurred. — Difficult to calibrate the effectiveness of oil recovery. — In deeper water, requires a vessel with a boom/pulley and adequate deck space on the stern for handling, inspection, and replacement. — Best suited for recovery of small amounts of oil.
Towed Nets or Trawls	
— Readily available in areas with commercial fisheries. — Experienced operators (fisherman) with vessels capable of effectively towing.	— Difficult to specify size of net openings, have to use what is available. — Leakage of oil through net may occur and hard to monitor. — Cannot be cleaned and returned for intended purpose, thus most likely will be a one-time use. — Will require support to handle/dispose of oiled nets. — May have issues with debris. — May snag on rocks or obstructions.
Manual Recovery Shallow Water	
— Low tech, only requires labor force and hand tools. — Selective recovery, limiting co-collection of water and sediment.	— Slow and labor intensive; requires proper PPE. — Restricted to shallow water <5 ft. — Requires relatively good water clarity for visibility. — Severe weather will suspend operations.

Table 6—Advantages and Disadvantages of Sunken Oil Recovery Technologies (Continued)

Advantages	Disadvantages
Manual Recovery with Divers	
— Relatively low tech, requires divers and hand tools. — Selective recovery, limiting co-collection of water and sediment.	— Slow and labor intensive. — May require extensive logistical support if based off vessel or barge. — Requires properly trained commercial diving crew with contaminated-water diving equipment. — Requires decontamination equipment and trained support personnel. — Severe weather will suspend operations.
Agitation/Refloat	
— Off the shelf items such as pumps and rakes can be used. — Aerators designed for waste water treatment or fish ponds can be modified for sunken oil recovery. — Selective recovery limiting associated recovered water and sediment.	— Slow and labor intensive. — Small coverage area. — Restricted to shallow water <8 ft and relatively low water velocity. — Suspended oil can remain mixed with the sediments and resettle to the bottom after agitation. — Mixes remaining oil deeper into the sediments. — Only effective with liquid oils that are loosely adhered to the sediment and will re-float when separated from the sediment, and where complete containment of the resuspended oil is possible. — Generates high turbidity that can spread downstream.

Table 7—Summary of Sunken Oil Recovery Technologies

	Suction Dredge	Diver-directed Pumping and Vacuuming	Mechanical Removal
Description	Commercially available suction dredge used to recover sunken oil and associated sediments and water. Some models incorporate cutter heads for use in removing sediments.	Divers manually direct a nozzle or stinger at the suction end of a hose to recover sunken oil. System can be based on a vacuum system or pump system utilizing a centrifugal or positive displacement pump.	Mechanical removal involves physically removing sunken oil with an excavator, clamshell dredge, environmental dredge bucket, or other machinery used to grab, scoop, or pick up sunken oil. Works well for recovery of solid or semi-solid sunken oil.
Logistical Needs	Requires the need to handle large quantities of sediments and water associated with recovery.	Contaminated water capable commercial divers, proper diver decon, oil/water/sediment separation and storage.	Platform or barge to work from and hopper barge or suitable storage for recovered sunken oil and associated sediment and water.
Operational Limitations	Smaller units work in depths up to 20 ft, larger units can go as deep as 40 ft. Suited for protected waters only.	Vacuum systems can only lift about 28 ft total. Pumps can push long distances and from great depths.	Excavators are limited to ±20-ft depth. Clamshell and environmental clamshell dredge can work in deeper depths but difficult to control accuracy. All can be operated from shore or from large vessel or barge.

Table 7—Summary of Sunken Oil Recovery Technologies (Continued)

	Suction Dredge	Diver-directed Pumping and Vacuuming	Mechanical Removal
Optimal Conditions	Protected water, relatively shallow, small concentrations of sunken oil.	Larger concentrations "pooled" on the bottom in less than 100-ft depth with good visibility and little to no current.	Viscous or solidified oils in shallow or protected water.
Pros	Effective way to recover small concentrations of sunken oil mixed throughout sediments.	Selective recovery, diver can distinguish between sediment and oil limiting the recovery of associated sediment and water.	Effective way to recover solidified oil with little associated water.
Cons	Generates large amounts of associated water and sediments. Requires sophisticated oil water separation, and treatment/ disposal of oiled sediments and water.	Vacuum systems effectiveness decreases with hose length, centrifugal pumps tend to emulsify and shear oil, complicating separation after recovery; positive displacement pumps recover at slower rates.	Requires geo referenced program to control accuracy. Can end up with large amounts of associated sediments. Disturbs bottom, so may be restricted in sensitive benthic habitats.
	Sorbents/V-SORs	**Manual Removal**	**Agitation/Refloat**
Description	Sorbent material are weighted or attached to a pipe/chain and dragged along the bottom allowing sunken oil to adhere to oleophilic material.	Hand and hand tools are used to pick up viscous oil on the bottom. Can be conducted in shallow water by wading; in deeper water by divers in gear appropriate for contaminated water.	Bottom sediments are agitated by physical disturbance or air injection to refloat the oil for recovery using skimmers or sorbents. Can be conducted from boats or by wading in shallow water.
Logistical Needs	Small V-SORs systems can be worked from smaller vessels; large V-SORs systems require larger vessel or platform.	For wading depths working from shore, need shoreline access, trafficable substrate, hand tools, and standard waste handling facilities. For diving depths, will need all logistics for contaminated water diving as well as waste handling and management.	May need sediment curtains or other containment methods to prevent oil migration down current. Other needs are standard: boats, pumps, booms, sorbents, etc.
Operational Limitations	While effective at any depth, accuracy and bottom contact suffer as water depth increases.	For wading depths, safety will drive wave, wind, rain, and lightning restrictions. Diving may be limited by depth and environmental conditions.	Limited to shallow water <8 ft, low-flow conditions, and standard limitations for on-water operations.
Optimal Conditions	Small or trace amounts of oil distributed along the bottom in less than 50 ft of water with little or no current.	Shallow water, good visibility, low currents, viscous oil that can be readily removed by hand.	Static water conditions, fresh oil that will be more easily liberated, and areas with good containment/recovery access.
Pros	Required materials are readily available. No associated recovered water or sediments.	Individual pieces of oil can be removed. Selective recovery, limiting co-collection of water and sediment. Can be low-tech, except where diving logistics are complicated.	May be the only alternative to dredging or excavation of oiled sediments. Does not require sediment or water handling and treatment.
Cons	Low recovery volumes, oiled solid waste generated for disposal. Placement accuracy decreases as water depth increases. Must contact oil/ bottom.	Slow and labor intensive. Requires relatively good water clarity for visibility. Diving may require extensive logistical support if work is offshore on vessel or barge. Will require contaminated water diving gear and decontamination of divers and gear. Severe weather will suspend operations.	Liberated oil may suspend in the water column and settle back to the bottom, with potential to spread down current. Can mix the oil deeper into the sediments during agitation.

Site Considerations

- ❑ Water depth range:_____
- ❑ Water visibility range: _____
- ❑ Water current speed and direction:

  Surface: _____

  Subsurface: _____
- ❑ Wave conditions: _____
- ❑ Water temperature: _____
- ❑ Substrate type:_____
- ❑ Bathymetry (oil accumulation areas):_____
- ❑ Sensitive habitats in survey area:_____

  Biological resources: _____

  Cultural/historic resources:_____

  Water intake/discharge locations: _____

Oil Property Considerations

- ❑ Oil viscosity/pumpability: _____
- ❑ Bulk oil on the surface:_____
- ❑ Volume of bulk oil on the surface: _____
- ❑ Risk of mobilizing oil into water column:_____

Equipment Considerations

- ❑ Sorbents/V-SORs
  - ○ Source of snare/pom poms (best with white sorbent materials)
  - ○ Fabricate chain and pipe
  - ○ Identify suitable vessel/platform
  - ○ Proper waste stream for oiled snare/sorbent
  - ○ GPS or tracking for proper documentation
  - ○ Photo documentation

- ❑ Manual removal
  - ○ Select suitable and ADCI certified commercial diving contractor(s) in full compliance with regulatory and industry standards (reference commercial diver safety checklist).
    - ▪ Minimum five-member diving team
    - ▪ Supplemental divers to ensure continuity of operations and adherence to work/rest requirements
    - ▪ Surface-supplied diving operations with CCTV and surface communications
    - ▪ Contaminated water diving capabilities
    - ▪ Decontamination equipment and procedures
    - ▪ Emergency plan that identifies on-site first aid and decompression capabilities
    - ▪ Adequate working platform to support safe entry and exit from the water
  - ○ Identify suitable support vessel/platform. Storage barges must be approved by the Unified Command prior to operations.
  - ○ Consider waste stream for recovered oil to include handling and storage. Decanting must be approved by the Unified Command in advance.
- ❑ Agitation/Refloat
  - ○ Options for agitation; pumps, compressors, aerators etc.
  - ○ Segregate areas with containment and sorbent boom.
  - ○ Identify method of recovering refloated oil.
  - ○ Waste stream considerations for recovered oil to include handling and storage.
  - ○ Storage barges and decanting procedures must be approved by the Unified Command in advance.
- ❑ Suction Dredge
  - ○ Identify suitable dredge type and qualified contractors.
  - ○ Determine estimated volume of water/sediment/oil to be recovered.
  - ○ Identify suitable site for handling separation of sediment/oil/water retention ponds, geotubes.
  - ○ Waste stream considerations for water/oil/solids to include separation and storage. Storage barges and decanting procedures must be approved by the Unified Command in advance.

- ❑ Diver-directed Pumping and Vacuuming
  - ○ Determine whether vacuum will work (hose lengths to be used) or pumping.
  - ○ Select suitable and ADCI certified commercial diving contractor(s) in full compliance with regulatory and industry standards (reference commercial diver safety checklist):
    - ▪ Minimum five member diving team
    - ▪ Supplemental divers to ensure continuity of operations and adherence to work/rest requirements
    - ▪ Surface-supplied diving operations with CCTV and surface communications
    - ▪ Contaminated water diving capabilities
    - ▪ Decontamination equipment and procedures
    - ▪ Emergency plan that identifies on-site first aid and decompression capabilities
    - ▪ Adequate working platform to support safe entry and exit from the water
  - ○ Select appropriate vacuum system/truck or centrifugal and positive displacement pumps.
  - ○ Identify suitable vessel/platform to work from if not accessible from shore.
  - ○ Waste stream considerations for water/oil/solids to include separation and storage. Storage barges and decanting procedures must be approved by the Unified Command in advance.
- ❑ Mechanical Removal
  - ○ Identify method; excavator, clamshell, environmental clamshell.
  - ○ Identify suitable vessel/platform to work from if not accessible from shore.
  - ○ Waste stream considerations for water/oil/solids to include handling and storage.

6 Waste Stream Management

Managing the oil, water, silt, sediment, and debris waste stream collected during sunken oil response operations is often complex given the multiple variables involved, including oil characteristics, temperature, volumes, recovery system, and pumping method and pumping rates. Unfortunately, there is not a one-size-fits-all decanting or waste stream management system to address all types of oils and environmental conditions. Historically, waste stream management systems have been designed ad-hoc following the discovery of a submerged oil incident and tailored to the specific conditions encountered throughout the operation. As such, adaptability and variability can be expected in the development of a waste stream management system for sunken oil recovery.

Table 8 provides an overview of options for the treatment and management of waste streams associated with sunken oil recovery techniques. The most common and proven system used during sunken oil recovery operations involves the process of phase separation using a series of decanting tanks with the final water phase entering a filtration or “polishing tank” prior to discharge.

NOTE The waste management and decanting plans must be approved by the Unified Command prior to commencing operations.

Table 8—Options for Treatment of Waste Streams from Sunken Oil Recovery Operations

Process Phase	Description	Comments
Phase Separation	Solid Separation	Baffled/Gravity Settling Tank
		Lamella Clarifier
	Liquid Phase Separation	Heat or air may be applied
		Diffused Air Flotation
	Oil Skimmer	
Centrifuge	Physical Separation	
Voraxial Separator	Cyclonic Separation	
Electrocoagulation	Electrical/electron separation	
Media Filtration	Sorbent Material	
	C.I. Agent	
	Imbiber Beads	
Emulsion Breakers	Demulsifier to improve oil-water separation	Consider environmental trade offs
Storage	Regulatory approved tank vessels	Sufficient capacity to store pumping discharge

The following key points should be considered when developing a waste stream management plan.

— The use of tanks with baffles will reduce the free surface effect, speed up oil/water separation, and prevent re-mixing.

— All waste management system tanks should be inspected prior to operation to ensure no residual contamination is present.

— If any part of the waste stream management system is overwhelmed, response operations may be suspended or delayed until sufficient capacity becomes available. The waste stream management plan should consider sufficient back-up storage capacity to ensure continuity of operations.

— Agitation of the system, through vessel movement or pumping, can result in oil emulsions that hinder effective separation and delay waste stream processing. Waste stream management systems should be placed on a stable platform such as a spud barge or jack-up rig. Pumping systems should be regulated to minimize agitation. Additionally, contingency plans should identify receiving vessels with sufficient capacity to store pumping discharge.

— Regional decanting policies vary. For example, many states permit direct decanting of oil into a boomed area on-site while others require media filtration or “polishing” of the effluent with analysis of the outflow. Periodic or continuous analysis of effluent may also be a requirement of a discharge permit. The decision when to decant may also be dependent on whether or not sensitive resources could be affected by the discharged water.

— The state or regional specific decanting checklist should be completed under the direction of the Unified Command in advance of operations.

— Standard phase separation with final water filtration has proven effective on sunken oil recovery operations. Pump selection, pumping rates, and phase separation tanks can be modified to improve system efficiency. As such, responders should consider mobilizing various pump options to expedite operations.

7 Safety Considerations

The detection and recovery of sunken oil require equipment and technical specialists not used during surface oil recovery operations. As the safety of life is consistently the top priority and objective during every oil spill response, responders should focus on taking proactive measures to ensure the safety of response personnel and the public throughout the operation.

The following safety checklists provide an overview of safety issues to address when developing a plan to conduct sunken oil detection and recovery operations.

General Safety Checklist

- ❑ Designate an Assistant Safety Officer with experience in diving, subsea, and offshore operations to oversee on-site operations and to support the Unified Command's safety planning efforts.
- ❑ In addition to reviewing the site-specific safety plan, decontamination plan, medical plan, communications plan, waste disposal plan, and heavy weather contingency plan, personnel must complete a Job Hazard Analysis (JHA) prior to every operational period and when work tasks or environmental conditions change.
- ❑ Personnel assigned to the sunken oil recovery project should be experienced and properly trained. For example, personnel conducting the mobilization of equipment and heavy lift operations should maintain OSHA rigger and signalperson certifications, and the crane operator should also maintain a recognized crane operator certification. Personnel working on-site should maintain certifications in accordance with the Hazardous Waste Operations and Emergency Response (HAZWOPER) standard found in Title 29 of the *Code of Federal Regulations* (*CFR*) 1910.120.
- ❑ All personnel working on-site should wear the required personal protective equipment to prevent exposure and injury, including hard hats, hearing protection, safety glasses, boots, coveralls/Tyvek®, appropriate gloves, and approved life jackets or work vests when working near water.
- ❑ Air monitoring operations should be conducted for respiratory protection and to collect data for daily reports.
- ❑ Respiratory protection should be available and used by properly trained personnel, as required.
- ❑ Personnel should not work alone on shore or on deck and workers should be equipped with adequate communications equipment for emergency purposes.
- ❑ The site-specific medical and safety plans must identify adequate nearby medical facilities and the best travel routes from the project site.
- ❑ First aid equipment must be readily available on the project site.
- ❑ Workers should have current first aid, CPR, and AED certifications and receive a briefing on the safety and medical plans prior to commencing operations.
- ❑ An adequate work/rest cycle should be implemented in an effort to prevent fatigue and accidents.
- ❑ Environmental conditions must be reviewed and considered daily in an effort to ensure workers are properly protected and remain comfortable to perform the required work.

- ❑ Vessels and equipment should be certified for their intended use with up-to-date inspection and/or certification records.
- ❑ Onboard lifesaving and firefighting equipment may need to be supplemented to support additional project personnel and equipment.
- ❑ Aerial heavy lift and personnel transfer operations should also be reviewed to ensure alignment with Office of Aviation Services (OAS) guidelines.

Equipment Mobilization and Heavy Lift Operations Checklist

- ❑ Review crane certification records and annual inspection reports.
- ❑ Ensure all rigging and slings are certified and in good condition.
- ❑ Ensure all Riggers and Signalpersons have completed OSHA required training.
- ❑ Ensure all personnel operating heavy lift equipment are Certified Crane Operators.
- ❑ If lifting operations will be completed from a barge or lift boat, ensure the crane's load chart reflects the integration of the vessel and lifting device and that the vessel's stability letter supports the addition of the crane.
- ❑ Prepare a lift plan that includes the lifting device load chart.
- ❑ Personnel must wear PPE, specifically hard hats when working around lifting operations and hearing protection when working around energized equipment.
- ❑ All personnel operating forklifts should have completed the OSHA required training and maintain a current certification.
- ❑ Prior to lifting, ensure overhead and intended lifting path are clear and safe for operations. The swing radius of the crane should be barricaded to prevent personnel from walking through the area.
- ❑ Conduct pre-use equipment inspections prior to operations in association with the daily JHA process.
- ❑ Weather is a primary source of dynamic loading and should be considered prior to conducting heavy lifts.

Hydraulic Submersible Pumps and Transfer Operations Checklist

- ❑ Equipment should have annual equipment inspection documents and an on-site inspection prior to each transfer operation.
- ❑ Inspect discharge hoses prior to each use and review documentation of the annual static liquid pressure test to 1.5 MAWP.
- ❑ Hose connections must be 4-bolted, full-threaded, or a quick-connect coupling approved by the U.S. Coast Guard.

- ❑ Face shields should be worn when connecting/disconnecting hydraulic lines.
- ❑ To prevent hydraulic oil spills, drip pans should be placed below hose connections and the hydraulic power unit should be placed within containment.
- ❑ Hydraulic hoses should be routed to prevent slips, trips, and falls.
- ❑ Complete a Declaration of Inspection in accordance with 33 *CFR* 156.150 prior to transfer operations.
- ❑ Review emergency shutdown procedures as part of the DOI and JHA.
- ❑ Personnel should wear eye and hearing protection, gloves, boots, and coveralls when working in the vicinity of hydraulic power units and pumping systems.
- ❑ Respiratory protection should be worn in hazardous atmospheres by properly trained and fit-tested personnel as required by on-site air monitoring.

Diving Operations Checklist

- ❑ Conduct all diving operations in accordance with 46 *CFR* 197, 29 *CFR* 1910 and Association of Diving Contractors International (ADCI) standards.
- ❑ Obtain Unified Command approval of Diving Operations Plan, Site Safety Plan, Decontamination Plan, and Disposal Plan, among others.
- ❑ The dive team should consist of at least five members, including an ADCI certified non-diving Supervisor and four ADCI certified divers.
- ❑ Each diver should have documentation of current HAZWOPER, CPR, O_2 administration, first aid certifications, and ADCI Certification Card.
- ❑ Conduct diving operations with a surface-supplied breathing gas supply and an umbilical that includes communications, CCTV, and a pneumo-fathometer.
- ❑ All equipment should have at least annual inspection documents with the exception of depth gauge calibrations and compressor air quality analysis that must be completed every six months.
- ❑ Breathing gas supply hoses must have a rated bursting pressure of four times the rated working pressure and tested annually to 1.5 MAWP.
- ❑ The Diving Supervisor should conduct a pre-dive inspection of all equipment in association with the JHA. The Diving Supervisor must brief the dive crew on the planned diving operation and risk mitigation procedures.
- ❑ Maintain a dive log that includes a depth-time profile for each diver including: diver name and designated person-in-charge; date, time and location; diving mode used; nature of work performed; surface and subsurface conditions; and maximum depth and bottom time. For each dive outside no-decompression limits, greater than 100 fsw, or using mixed gas, record the following: depth-time and breathing gas profile; decompression table designation and any modifications; and elapsed time since last pressure exposure if less than 24 hours or repetitive dive designation for each diver. If decompression sickness is suspected or symptoms are evident, the decompression sickness, depth, and time of onset, and description and results of treatment should be recorded.

- ❑ Locate compressor intakes away from hazardous atmospheres. Conduct continuous air monitoring to confirm air quality is safe for diving operations.
- ❑ Mark umbilicals at 10-ft increments to 100 ft and then every 50 ft thereafter.
- ❑ Conduct diving operations in accordance with U.S. Navy standard or approved contractor decompression tables.
- ❑ Limit surface-supplied air diving operations to 190 fsw, with brief excursions of less than 30 minutes permitted to 220 fsw.
- ❑ Divers must carry a reserve breathing gas supply and be continuously tended from the surface.
- ❑ First Aid equipment, including a hand-held resuscitator, must be located on site. An on-site Automated External Defibrillator (AED) is also recommended.
- ❑ Provide a diving ladder or stage to allow the diver safe access to the water.
- ❑ A decompression chamber must be on-site for diving operations of 100 fsw or more, or for diving operations outside the no-decompression limits. A decompression chamber should also be considered for conducting operations in remote locations or offshore where access to on-shore treatment is not readily accessible.
- ❑ Procedures must be implemented and strictly enforced to prevent oil and other contaminants from entering a hyperbaric chamber. Oil contamination is a fire hazard in a hyperbaric chamber. Additionally, oil contamination poses a respiratory hazard for personnel in a hyperbaric chamber.
- ❑ Display an Alpha Flag at least 3 ft in height to warn other vessels of diving operations.
- ❑ Provide contaminated water diving equipment for at least the diver and standby diver. Additionally, dive support personnel should be provided sufficient PPE to prevent contamination.
- ❑ Divers operating in contaminated water should be sufficiently trained and experienced in dry-suit diving and the required decontamination and emergency response procedures.
- ❑ Set up a decontamination station that is properly equipped and attended with personnel in the appropriate PPE prior to conducting diving operations.
- ❑ Hand-held tools and hydraulic submersible pumps must be de-energized before entering and exiting the water. Underwater tools and pumps should only be energized at the request of the diver.
- ❑ Diving in contaminated water, rivers/high currents, and arctic/cold water conditions are considered hazardous operations. Divers should be properly trained and experienced prior to attempting these operations. Refer to the Technical Report for additional recommendations and guidance on diving in these high-risk environments.
- ❑ As this checklist is not all-inclusive, for additional information on diver life support systems, please refer to the *ADCI Consensus Standards*, Section 6.0, entitled “Life Support Equipment: Requirements, Maintenance, and Testing”.

Crude Oil Study

2018

Final Bakken Crude Oil: Worker Health and Safety Pilot Scale Studies (April 30, 2018 Rev 0.1)

Table of Contents

Executive Summary

1. Background/Purpose

1.1 Cold Weather Scenario

1.2 Warm Weather Scenario

2. Monitoring/Sampling Equipment and Technique Overview

2.1 Crude Oil Sampling

2.2 UltraRAE 3000 for Benzene

2.3 Tedlar® Bags for Benzene

2.4 Trace Atmospheric Gas Analyzer (TAGA) Monitoring

2.5 Charcoal Tubes

2.6 AreaRAE

2.7 MultiRAE

2.8 TVA 1000B

2.9 Water Sampling and Analysis

3. Site Monitoring/Sampling Activities

3.1 Cold Weather Scenario

3.2 Warm Weather Scenario

4. Results

5. Discussion of Variability

6. Conclusions

7. Items for Further Investigation

Executive Summary

Due to an increase in the amount of crude oil transported by rail in the United States over the past 10-years, more oil spills have occurred by rail. The geographic reach of rail transport creates a greater need to develop information to assist first responders with safety concerns during early actions at these spill sites. In support of this effort the US Environmental Protection Agency (EPA) designed and conducted cold and warm weather scenarios involving "spill" episodes to water.

Two ambitious study scenarios were designed as trial studies to determine several seasonal differences in chemical emissions from water, compare real-time air monitoring screening instrument results with definitive air sampling results, compare crude oil weathering in salt water with cold weather, and compare the impact of turbulent vs still water conditions on emission rates from the oil spill. The cold weather and warm weather scenarios generated many important results. These results in turn help to inform the direction for follow-up studies that EPA and/or other federal agencies may consider.

The composition of the Bakken Crude Oil used for the Cold and Warm Weather Scenarios was consistent with other crude oil samples from the same region; however, Bakken Crude Oil is not a consistent product and crude oil can show different flashpoints depending on the fraction of highly volatile organic compounds (VOCs) present in the crude oil. Although field measurements immediately adjacent to the spill and just after the release of the Bakken Crude Oil did not produce total VOC concentrations that pose an explosion concern for first responders, oxygen levels were identified that would necessitate the need for first responders to use supplied air during this relatively brief period.* Additionally, it is critical for first responders to approach oil spills with a combustible gas meter for measurement of oxygen and explosive levels. While not noted in this study, hydrogen sulfide should also be monitored, as its content can vary by shipment. Initial approach from the upwind side of the oil spill is highly recommended. When monitoring indicates acceptable oxygen levels, the first responders may then consider the use of air-purifying respirators with appropriate cartridges.

There were significant differences in airborne benzene concentrations as indicated by air monitoring and co-located air sampling equipment. These differences were more pronounced in the Warm Weather Scenario than the Cool Weather Scenario. The emission rate of VOCs including benzene as determined by air monitoring and sampling were greater in warm weather than in cool weather. Benzene levels under all study conditions declined to less than 0.1 parts per million (ppm) within 4-hours of the oil release to water, while airborne total VOC levels remained elevated at low ppm numbers for nearly 24-hours. Based on the common VOCs present, their airborne concentrations were not above identified worker exposure limits; however full-face air purifying respirators with appropriate cartridges wore worn throughout the initial 24 hour period. The emission rate of VOCs including benzene determined by similar air monitoring and air sampling methods was greater in turbulent water conditions than in still water conditions as investigated during the Warm Weather Scenario.

As part of potential future work, EPA would like to further investigate additional real-time monitoring equipment for use during oil spill episodes and further characterize emissions during the first several hours following an oil spill. Current results indicate that the flame ionization detector shows significantly higher emission rates than for the photoionization detector. This is particularly evident during the initial hours after the spill. This suggests appreciable emissions of short-chain VOCs may be present and contain gases that cannot be measured by the photoionization detector that was used but are measured by the flame ionization detector.

* Note, these tests were of a small spill and in open air conditions. For larger spills and non-open air conditions such as culverts and tunnels, etc, atmospheric concentrations may be much higher.

1. Background/Purpose

Response to inland oil spills that threaten waters and sensitive environments is one of the responsibilities of the EPA. Two studies were performed by EPA's Environmental Response Team (ERT) with the assistance of the Scientific, Engineering, Response and Analytical Services (SERAS) contract program to further the knowledge base for those responding to oil discharges that pose a threat to human health and/or the environment. While significant testing has been performed by different organizations on crude oil produced from the Bakken formation, the testing is generally comprised of standard petroleum characteristic analyses and characterization for proper transportation based on Department of Transportation (DOT) classifications. The data from these testing programs have provided critical knowledge for classifying and understanding standard properties of hazardous materials – in this case, a light, sweet crude oil. However, many questions require additional attention and study. These oil discharge occurrences have resulted in a loss of human life and damage to the environment. The response community continues to raise concerns at all levels of government in light of the spills, well blowouts, major derailment events and associated fires, oil releases to the environment, and loss of life and damage that have occurred.[1] [2] [3]

The DOT and Department of Energy (DOE) recently published findings from an extensive literature review focused in part on Bakken Crude Oil that supports Bakken oil samples containing a high gas content and typically containing more light volatile fractions than many other light crude oils.[4] The potential for more oil spills is a reality due to greatly increased railcar transport of crude oil in recent years in the United States. In 2008, railroads transported approximately 10,000 railcars of crude oil. By 2014, the railroad industry transported approximately 500,000 railcars of crude oil.[5] This dramatic increase in railcar transportation of crude oil is among the factors that has led to many more crude oil accidents. The transportation of Bakken Crude Oil poses a greater fire concern than heavier crude. Aside from the fire concern, oil spills pose a health concern to responders, the community, and the environment.

Two studies were performed, a Cold Weather Scenario in February 2015 and a Warm Weather Scenario in June 2016. Personnel from multiple EPA Regions, EPA ERT, and their contractors worked together to conduct air monitoring and sampling, initial bulk sampling of the Bakken Crude Oil and sampling at time periods subsequent to spill episodes. Limited sampling of the water column at several depths was performed for crude oil components during the Warm Weather Scenario. The primary purpose of these Pilot Scale Studies was to determine air concentrations, under observed meteorological conditions, of benzene in Bakken Crude following spills to water. The resulting information helps to inform initial decision-making and thereby better protect workers involved in a Bakken Crude Oil release response.

[5] C. Krauss and J. Mouawad, Accidents Surge as Oil Industry Takes the Train, New York Times, reported, January 25, 2014,

Benzene was the main contaminant of concern, as it has the lowest worker exposure limits among common VOC emissions from crude oil. Baseline benzene concentrations were measured in the Bakken crude prior to and after the Bakken Crude Oil emissions studies. The benzene concentrations in the crude can then be used to correlate with the benzene air concentrations. Monitoring and sampling methodologies were chosen based on the air monitoring and sampling instruments that first responders commonly use. Additionally, benzene has the lowest exposure limits of common volatile emissions from crude oil and would drive several respiratory protection and personal protective equipment (PPE) decisions.

General study conditions for the Pilot Scale Studies are provided in **Table 1** including a comparison of conditions along with the monitoring and sampling performed during each study. In addition to providing some initial information that may help First Responders in their decision making process, this report also details sampling and analytical methods relevant to oil spill episodes and identifies issues worthy of additional study. Note that monitoring and sampling parameters differed for the two different scenarios.

1.1 Cold Weather Scenario

The Oil and Hazardous Materials Simulated Environmental Test Tank (OHMSETT) Facility in Leonardo, New Jersey (NJ) was used as the site of a simulated oil spill during cold weather. (See **Figure 1**, below.) One week before the cold weather study, approximately 1,675 gallons (11,280 pounds) of Bakken Crude Oil was loaded on to a tanker truck in Eddystone, Pennsylvania (PA). A pre-shipment sample of that oil was collected. When the tanker truck arrived at the OHMSETT Facility in Leonardo, NJ, a sample of post shipment oil was collected during the transfer from the tanker truck to the storage totes. The oil in the tanker truck was transferred to five 330-gallon steel totes.

On the release day, 330 gallons of Bakken Crude Oil was released at 10:11 hours and again at 10:23 (for a total of 660 gallons or two totes) into a boomed section of the OHMSETT salt water tank. The tank and boomed area measured 100 feet (ft) by 65 ft by 7 ft deep. Just prior to the release an oil sample was collected. The oil was allowed to spread and move in accordance with ambient meteorological conditions. Weathering of the oil continued in to the next day (February 12, 2015) when at 8:31 a sample of the weathered oil was collected. (In a water spill, weathered crude oil has lost many of its more volatile components and some mixing occurs with surrounding water.[6])

Air monitoring and sampling were performed on three days: background (February 10, 2015), release (February 11, 2015) and skimmer test day (February 12, 2015).

Table 1
Cold and Warm Weather Scenario Comparison
Bakken Crude Oil: Worker Health and Safety Pilot Scale Study

Scenario	Cold Weather Scenario	Warm Weather Scenario
Dates	February 11 to February 12, 2015	June 14 to June 16, 2016
Air Temperature Range	21 to 39 degrees F (ºF)	54 to 85 ºF
Spills & Description	1 Spill of 660 gallons - Ambient (still) conditions	1 Spill of 55 gallons - Ambient (still water conditions) & 1 Spill of 55 gallons (induced turbulent conditions) in 2 different tanks
Location	OHMSETT Facility, Leonardo, NJ	Somerset County ESTA, Hillsborough, NJ
Size	100 ft by 65 ft	10 ft by 10 ft
Pool Type	Concrete and boom wave tank	Portable Fire Department drafting tank
Water type	Salt	Fresh
Depth of water	~7 feet	18 to 21 inches
Fixed Air Monitoring	Perimeter VOCs by PID, H_2S	Perimeter VOCs by PID, H_2S
	Perimeter LEL calibrated to methane	Perimeter LEL calibrated to pentane
Fixed Air Sampling	NIOSH Charcoal Tube Method	None
Mobile Air Monitoring (based on wind direction)	Benzene (on UltraRAE)	Benzene (on UltraRAE)
	None	VOCs by PID, H_2S
	None	LEL calibrated to pentane
	None	LEL calibrated to methane
	None	VOCs by FID
TAGA, Benzene	Air Monitoring was performed on line to west of pool spill and above the ASTM skimmer tests.	Air Monitoring performed at three different lines downwind of the tanks.

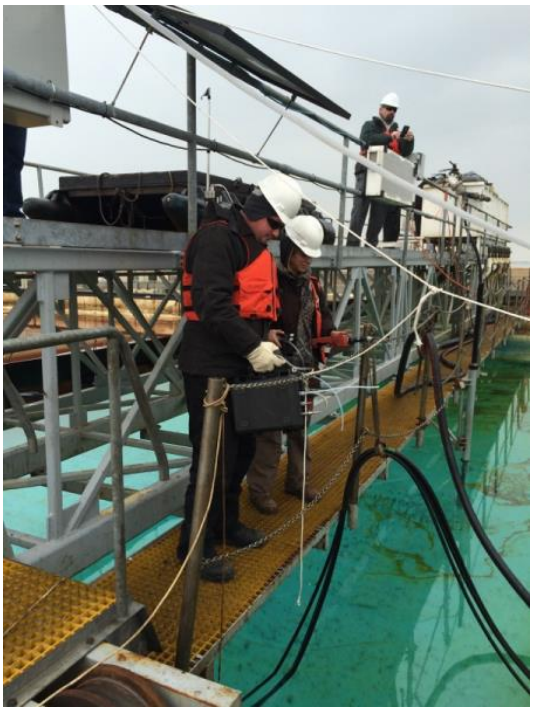

Figure 1- Cold Weather Scenario, OHMSETT

1.2 Warm Weather Scenario

After the February 2015 study, three totes of this Bakken Oil remained at the OHMSETT Facility in Leonardo, NJ. The viability of the stored oil was tested in May 2016 and based on the results, EPA determined that the oil was suitable to perform the study.

On June 14, 2016, the Bakken Crude Oil stored in Tote 3 at the OHMSETT Facility in Leonardo, NJ was transferred into 55-gallon drums, transported to the Somerset County Emergency Services Training Academy (ESTA) arriving at approximately 10:00.

Two folding frame tanks manufactured by Husky Portable Containment (Bartlesville, Oklahoma) were used for the study scenarios. These particular tanks are capable of holding 1,500 gallons of water and measured approximately 10 ft by 10 ft and 29 inches (in) in depth. For the Still Water scenario the average depth was approximately 21 inches giving an approximate volume of 1300 gallons. A fire hydrant on the ESTA facility provided the necessary fresh water to fill the two tanks.

The Still Water scenario started on June 14, 2016 and approximately one 55-gallon drum of Bakken Crude Oil was released between 11:45 and 11:54 into the tank at the northwest corner. Just prior to the release, an oil sample was collected at 11:45 during the transfer of the oil to the tank. The oil was allowed to spread and move in accordance with ambient meteorological conditions.

Figure 2- Warm weather event at Somerset County ESTA at the beginning of the introduction of the Bakken Crude Oil to one of the folding frame tanks.

The oil weathering continued into the next day (June 15, 2016). At 13:15 on June 15, 2016, SERAS personnel collected another oil sample. This sample was collected at the oil surface from the southeast corner of the tank and transferred to sample jars by utilizing pipettes.

For the Turbulent Water scenario, water depth measurements were not collected. The water level was observed to be lower in the second tank when compared to the first tank and it was estimated that the second tank contained between 1,100 and 1,200 gallons of water. The Turbulent Water scenario was used to simulate conditions of a flowing stream. It was hypothesized that these conditions would enhance volatilization.

Submersible pumps were placed in the northwest and the southeast corners of the tank to generate turbulence. The northwest pump (Everbilt), was manufactured by Homer TLC, Inc. (Wilmington, Delaware) and was capable of a flow rate of 1,400 gallons per hour. This pump's outflow was directed to the southeast. The southeast pump was manufactured by Flotec (Delavan, Wisconsin) and was capable of moving 1,320 gallons of water per hour. This pump's outflow was directed to the west. Both pumps were started prior to the oil release.

On June 15, 2016, the Turbulent Water scenario began as one 55-gallon drum of Bakken Crude Oil was released between 10:30 and 10:35 into the northwest corner of the tank. Just prior to the release, an oil sample was collected at 10:30 as the oil was transferred to the tank. The oil moved in accordance with water flow and ambient meteorological conditions. The oil weathering and sampling continued into the next day. At 7:58 on June 16, 2016, SERAS personnel collected another oil sample. This sample was collected from the northeast corner of the tank and was transferred from the surface of the oil to sample jars utilizing pipettes.

Table 2 presents a comparison of oil sample results along with the flashpoint results from each study.

Table 2
Oil Sampling and Flash Point Results
Bakken Crude Oil: Worker Health and Safety Pilot Scale Study

	Cold Weather Oil Samples			Warm Weather Oil Samples

(1) Drum sample from OHMSETT Tote 3, delivered to Somerset County Emergency Services Training Academy 6/14/16.

µg/g = micrograms per gram. U = Not detected.

-- = Not applicable or not analyzed.

* - From the MSDS which lists the flash point at 32 degrees Fahrenheit (°F).

Note: High post Reporting Limits from the June 2016 samples does not allow for comparison to Feb 2015 samples

2. Monitoring/Sampling Equipment and Technique Overview

Monitoring and sampling of Bakken crude, Bakken Crude Oil emissions, and water column analysis for Bakken Crude were performed in the course of the Bakken Cold and Warm Weather Scenarios. The weathered Bakken Crude was analyzed for benzene content as part of crude oil fingerprinting.

2.1 Crude Oil Sampling

All oil samples were collected in a manner consistent with SERAS Standard Operating Procedure (SOP) #2010, *Tank Sampling*. Bakken Crude Oil samples were collected prior to the first spill and then "weathered" crude oil samples were also collected 24 hours following the spill.

For the Cold Weather Scenario a weathered crude oil sample was also collected 7-days after the initial spill for oil fingerprinting and flashpoint determination. The pre-spill, one-day weathered and seven-day weathered oil samples were submitted to a laboratory for flash point testing by American Society for Testing and Materials (ASTM) D92 - 12b, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester*. While attempting to determine the open cup flashpoint of the pre-spill sample, it caught fire and was lost. The lab utilized ASTM D93 - 15, *Standard Test Methods for Flash Point by Pensky-Martens Closed Cup Tester* to determine the flashpoint of the remaining samples. The pre-spill and seven-day weathered oil samples were re-submitted to the laboratory for flash point testing by ASTM D93 – 15. The results for these two samples did not logically agree with what would be expected. Due to a likely laboratory mix-up with sample identification flashpoint results for these two samples were interchanged.

For the Warm Weather Scenario, the concentration of benzene was determined for each sample in accordance with EPA Method 8260B, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry (GC/MS). The percentage of benzene lost was calculated by comparing the first sample from each scenario against weathered samples from each scenario.

Oil samples were submitted for flash point testing by ASTM International D56, *Standard Test Method for Flash Point by Tag Closed Cup Tester*. The flash point results should be considered screening data.

2.2 UltraRAE 3000 for Benzene

Point monitoring for benzene using the UltraRAE 3000 was done in tandem with grab air sampling using Tedlar® (Tedlar) bags. The UltraRAE 3000 (UltraRAE) manufactured by RAE Systems (San Jose, CA), was operated in a manner consistent with SERAS SOP #2134, *Operation of the UltraRAE 3000 Specific Compound Monitor.*

Air monitoring was performed using the UltraRAE at locations where co-located Tedlar bags were collected. Upon collection the Tedlar bags were analyzed on site. The monitoring duration was dictated by the ambient air temperature, as determined by the UltraRAE, and ranged from 40 to 90 seconds, while the sampling time was 60 seconds to fill the one-liter (L) Tedlar bags.

The UltraRAE is a portable, hand-held, programmable compound specific PID monitor designed to provide instantaneous exposure monitoring of benzene. The UltraRAE was calibrated using a 5 ppm standard of benzene in accordance with the manufacturer's specifications. The unit was configured with a 9.8 eV gas discharge lamp and a benzene separation tube. A new benzene separation tube was opened and inserted just prior to each monitoring event. The range of detection for benzene is 0.05 parts per million (ppm) to 200 ppm.

2.3 Tedlar Bags for Benzene

Grab air samples using Tedlar bags were collected in accordance with SERAS SOP #2102, *Tedlar Bag Sampling*. These were analyzed for benzene aboard the onsite TAGA Mobile Laboratory using SERAS SOP #1741, *Field Analysis of VOCs in Gaseous Phase Samples by GC/MS Loop Injection.* An Agilent®7890 and 5975C Triple Axis GC/MS was used to perform the analysis, with results provided the day samples were collected. All analytical data were verified per definitive data (DD) requirements.

2.4 Trace Atmospheric Gas Analyzer (TAGA) Monitoring

Air monitoring for benzene was performed in accordance with the SERAS SOP #1711, *Trace Atmospheric Gas Analyzer (TAGA) IIe Operations*. Real-time monitoring for benzene was performed using a selected ion technique. The TAGA IIe is based upon the Perkin-Elmer API 365 mass spectrometer/mass spectrometer (MS/MS) and is a direct air-monitoring instrument capable of real-time detection of trace levels of many organic compounds in ambient air. The technique of triple quadrupole MS/MS is used to differentiate and quantitate compounds.

2.5 Charcoal Tubes

Charcoal tube samples were collected in a manner consistent with SERAS SOP #2103, *Charcoal Tube Sampling in Ambient Air*. The 8-hour samples were analyzed in a manner consistent with SERAS SOP #1816, *Indoor Air Analysis of Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry.*

2.6 AreaRAE

The AreaRAE (PGM-5020) was used for continuous monitoring near the oil spill area. VOCs, lower explosive limit (LEL), carbon monoxide (CO), hydrogen sulfide (H_2S), and oxygen (O_2) were measured. The AreaRAE was used in a manner consistent with SERAS SOP #2066, *Operation of the Area RAE Wireless Multi-Gas Monitor.*

2.7 MultiRAE Pro

The MultiRAE Pro units were utilized in accordance with SERAS SOP #2139, *Operation of the MultiRAE Pro Wireless Multi-Gas Monitor.* For VOCs (by PID) the MultiRAE Pro units were calibrated using either a 10 ppm or 100 ppm standard of isobutylene. Two units were utilized, one was calibrated with 0.75 percent (%) pentane and the other was calibrated to 2.5% methane (both respond as 50% of the LEL) in accordance with the manufacturer's specifications prior to deployment. Field calibrations were performed if instrument performance necessitated it. The MultiRAE Pro was only used during the Warm Weather Scenario.

2.8 TVA 1000B

The TVA-1000B Toxic Vapor Analyzer is a portable organic/inorganic vapor monitor used to survey for toxic gases during environmental and hazardous material responses. The analyzer uses either a photoionization detector (PID) or a flame ionization detector (FID), or both types of detectors to sample and measure gas concentrations. The PID was configured with a 10.6 electron volt (eV) gas discharge lamp. The range of detection for the PID is 0.5 ppm to 2,000 ppm. The range of detection for the FID is 1 ppm to 50,000 ppm. The TVA 1000B was only used during the Warm Weather Scenario.

2.9 Water Sampling and Analysis

Water samples were collected only during the still water Warm Weather Scenario. Samples were collected at five different locations within the folding frame tanks at different water depths and several different time points. The water sampling was conducted in a manner consistent with SERAS SOP #2013, *Surface Water Sampling*. The samples sent to the SERAS Analytical Laboratory were analyzed by SERAS SOP #1806, *Volatile Organic Analysis in Water by Gas Chromatography/Mass Spectrometry (GC/MS)*. The samples analyzed by the fixed and mobile laboratories were treated with procedures consistent with those specified in SERAS SOP #1008, *Sample Receiving, Handling, and Storage*, and all samples were stored on ice immediately after sample collection until analyses were performed or samples were transferred to a fixed refrigeration unit awaiting analysis.

3. Site Monitoring/Sampling Activities

The approaches, study parameters, and conditions were often different for the Cold Weather and Warm Weather scenarios, but some activities were done in a similar manner for both studies. These include:

Benzene Monitoring and Sampling

Air monitoring using the UltraRAE and sampling for benzene with Tedlar bags were conducted simultaneously. To ensure a complete data set collection, two Tedlar bag sampling trains were set up side-by-side; however, only one sample was submitted for analysis. Sampling information was documented on Tedlar bag sampling worksheets. Upon sample completion, each bag was placed into an opaque bag for transfer to the on-site GC/MS in groups of one to three samples along with the corresponding documentation. The grab air samples were collected in accordance with SERAS SOP #2102, *Tedlar Bag Sampling*.

TAGA Monitoring

Air monitoring for benzene was performed utilizing the TAGA. Both stationary and mobile monitoring were performed during each of the Cold and Warm Weather Scenarios.

Stationary Air Monitoring

For stationary monitoring, the AreaRAEs were either calibrated with 0.75% pentane or 2.5% methane (both respond as 50% of the LEL) in accordance with the manufacturer's specifications prior to deployment. Field calibrations were performed if instrument

performance necessitated it. For the cold weather scenario, the majority of the AreaRAE Units were calibrated to 2.5% methane. For the warm weather scenario, the majority of the AreaRAE Units were calibrated to 0.75% pentane.

All AreaRAEs were connected to ERT's wireless data acquisition system (VIPER). The VIPER system utilizes EPA ERT's VIPER Survey Controller application to manage data collection using Safe Environment Engineering's LifeLine (Valencia, California) wireless monitoring system. LifeLine is comprised of a Lifeline Interoperable Network Communicator (LINC) that is physically connected to an AreaRAE and connected to a Gateway via Wi-Fi. The Gateways provide a data connection from Survey Controller to the LINC through internet access using cellular air cards and Wi-Fi. The data were presented and archived on the ERT VIPER Deployment Manager website. The regional OSCs and ERT personnel were provided with access to site-specific monitoring data through the VIPER Deployment Manager website.

The VIPER Survey Controller application and the Deployment Manger website for this site were monitored by EPA and SERAS personnel while on-site to monitor for hardware or software issues. If a hardware or software issue was detected that needed on-site attention, SERAS personnel responded to the issue as quickly as possible.

3.1 Cold Weather Scenario

Benzene Monitoring and Sampling

During the Cold Weather Scenario, 25 Tedlar bag air samples were collected and analyzed for benzene on-site by SERAS personnel. Thirteen samples were collected on February 11, 2015 (Release Day) and 12 samples were collected on February 12, 2015 (Skimmer Test Day).

The same number of monitoring events with the UltraRAE were performed concurrently with the Tedlar bag sampling on February 11, 2015. Monitoring and sampling initially occurred next to the tote from which the oil was released. Monitoring and sampling locations were moved as meteorological conditions and MultiRAE Pro monitoring results warranted. One independent benzene air monitoring event occurred (without a Tedlar bag being collected) at the conclusion of the February 11, 2015 activities.

TAGA Monitoring

For the Cold Weather Scenario, the TAGA air monitoring events were conducted on February 11, 2015 and February 12, 2015, and were used for screening VOCs. Mobile TAGA air monitoring was performed at ground level on the western side of the OHMSETT tank on February 11, 2015. (See **Figure 3**.)

Stationary TAGA air monitoring was performed directly over the skimming operations at the OHMSETT tank on February 12, 2015. The TAGA was used to analyze outdoor air at the testing tank during stationary monitoring and mobile monitoring events. During mobile monitoring, one end of a 4-foot corrugated Teflon™ (Teflon) sampling hose was attached to the TAGA source inlet, while the other was attached to a glass transfer tube passing through the wall of the bus during the monitoring event. Mobile monitoring took place along the west side of the testing tank while the oil was released and collected using a skimmer. Stationary monitoring utilized a 300-foot corrugated Teflon sampling hose. The

proximal end was attached to the TAGA source inlet, while the distal end was taken over the testing tank and skimmer. In both cases, air was continuously drawn through the hose at a set flow rate and transported to the TAGA source during the monitoring event.

Stationary Air Monitoring

AreaRAE monitoring was initiated the day prior to the release (February 10, 2015) and continued through the afternoon of February 12, 2015. Eight locations were selected for air monitoring. As the focus of this study was nearby worker exposure, four points were located as close to the study area as possible, to the north (North Deck), east (East Deck), south (South Mobile Bridge) and west (West Deck). The remaining four points (North Fence line, OHMSETT Office, Southwest Corner of the Deck and South Fence line) were chosen as potential on-site and off-site migration or background locations. Two AreaRAEs were positioned on the South Mobile Bridge; these units were configured with the same sensors, one of the unit's LEL sensor was calibrated with methane and the other unit's LEL sensor was calibrated with pentane. **Figure 3** depicts the air monitoring locations.

Skimmer Tests with Weathered and Fresh Crude Oil

On February 12, 2015 (Skimmer Test Day), 12 benzene monitoring events were performed concurrently with the Tedlar bag grab sampling. Air monitoring and sampling occurred during four activities:

- During the recovery of the weathered oil from the initial 100 ft by 65 ft boomed area,
- Prior to and during the first ASTM Skimmer Test using recovered oil in a 10 ft by 10 ft boomed area near the northwest corner of the original test area,
- Prior to and during the second ASTM Skimmer Test using recovered oil from the same 10 ft by 10 ft boomed area, and
- Prior to and during a third ASTM Skimmer Test using only fresh oil in the same 10 ft by 10 ft boomed area.

On the morning of February 12, 2015, OHMSETT personnel collected the weathered oil from the 100 ft by 65 ft study area for a skimmer test. The skimmer test area was located in the northwest corner of the original study area and measured 10 ft by 10 ft. At 12:24 the collected weathered oil was dispensed to a 10 ft by 10 ft skimmer test area producing a three inch thickness of oil.

The first skimmer test of the weathered oil ran from 12:36 to 12:41. The second skimmer test of the weathered oil ran from 13:06 to 13:10. Prior to the third skimmer test the remaining weathered oil was removed from the 10 ft by 10 ft test area. From 13:39 to 13:42, fresh Bakken Crude Oil was dispensed into the skimmer test area. The third skimmer test ran from 13:46 to 14:00.

Approximately 60 gallons of oil that was collected during the skimming operations was returned to a smaller area within the tank and allowed to continue to weather. At 8:00 on February 18, 2015, OHMSETT personnel collected a sample of weathered oil into a mason jar. SERAS personnel were requested to retrieve this sample. On February 27, 2015, SERAS personnel traveled to the OHMSETT facility and transferred that sample into 40-milliliter (mL) vials at 9:00. **Attachment A** contains the report from the OHMSETT facility on the weathering and recovery of Bakken Crude Oil.

Figure 3- OHMSETT aerial, TAGA monitoring occurred on the west side of the pool.

Charcoal tube sampling for benzene

Charcoal air tube sampling for benzene was performed only as part of the Cold Weather Scenario. Time-integrated 8-hour samples were collected in accordance with the procedures referenced in Section 2. For this pilot scale study, the analysis was limited to benzene. Air sampling was performed on three days: February 10, 11, and 12, 2015. On all three days, the sampling was performed next to 7 of the 8 AreaRAE monitoring locations and are indicated in **Figure 3**. The only location where samples were not collected was at the OHMSETT Building Entrance. On February 12, 2017, additional sampling was performed during skimmer testing. At the end of each sampling day, the charcoal tube samples were collected and documented electronically in EPA's Scribe database. After documentation, the samples were stored in the refrigerator on EPA Mobile Laboratory Bus 1553 until they were hand delivered under chain of custody to the SERAS Laboratory on February 13, 2015.

3.2 Warm Weather Scenario

Benzene Monitoring and Sampling (under two water conditions)

During the Warm Weather Scenario, 31 grab air samples were collected in Tedlar bags and analyzed for benzene on-site by SERAS personnel. These grab air samples were collected as indicated previously. As with the Cold Weather Scenario, grab air sampling for benzene analysis occurred at the same time as point monitoring with the UltraRAE unit.

The "still water scenario" was conducted on June 14, 2016 and 14 benzene monitoring events were performed concurrently with the Tedlar bag grab air sampling. The final monitoring/sampling event occurred on the morning of June 15, 2016 and completed the still water scenario. Monitoring and sampling locations were based on meteorological conditions.

The "turbulent water scenario" was conducted on June 15, 2016 and 15 benzene monitoring events were performed concurrently with the Tedlar bag grab air sampling. The final monitoring/sampling event occurred on the morning on June 16, 2016 and closed out the turbulent water scenario. The monitoring and sampling event did not occur at the same time. Both Tedlar bags from one sample location did not fill and were not submitted for analysis; however, UltraRAE benzene monitoring was conducted at this time point.

TAGA Monitoring

For the Warm Weather Scenario TAGA air monitoring events were conducted on June 14, 2016 and June 15, 2016 for screening purposes. During each outdoor air monitoring event, the distal end of the 300-foot corrugated Teflon TAGA sampling hose held at breathing height and moved at a walking pace along a predetermined downwind path at ground level. (See **Figure 4**.) On each day, air was continuously drawn through the hose at a set flow rate and transported to the TAGA source during the monitoring event.

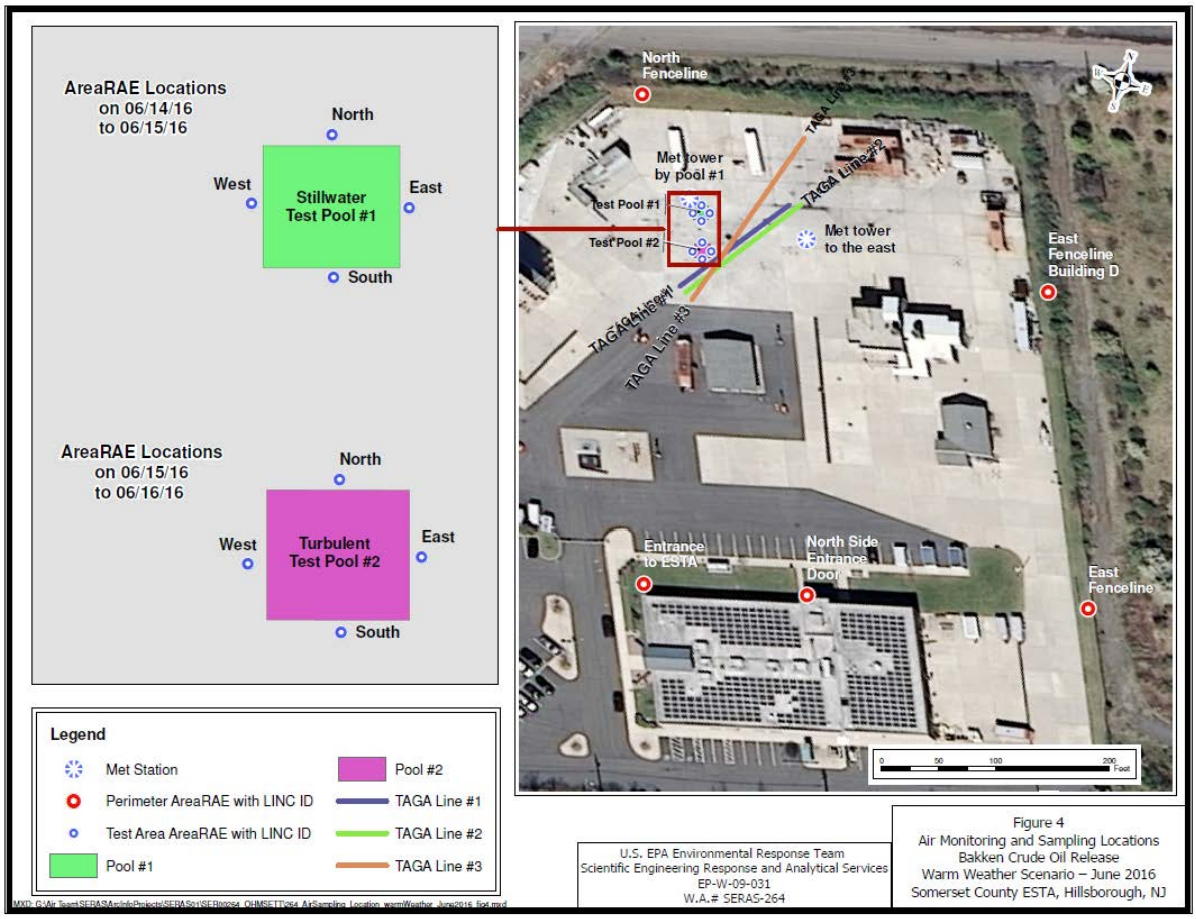

Figure 4- Somerset County ESTA, Three TAGA Monitoring Lines indicated south to east (downwind) of foldable tanks.

Stationary Air Monitoring

AreaRAE monitoring was initiated the day prior to the release (June 13, 2016) and continued through the morning of June 16, 2016. Nine locations were selected for air monitoring. As the focus of this study was nearby worker exposure, four monitoring points were located as close to the study area as possible; one each to the north, east, south and west of each tank. Prior to the Turbulent scenario the monitors were moved to the north, east, south and west of the second tank. The remaining five points (North Fence line, Entrance to ESTA, North Side Entrance Door, East Fence line and East Fence line Building D) were chosen as potential on-site and off-site migration or background locations. These last five locations remained the same for both scenarios. All AreaRAE LEL sensors were calibrated with pentane.

Water Sampling and Analysis

Water samples were only collected during the warm weather study during the Still Water sampling event. To establish a balanced spatial distribution, water sample locations were assigned to the center and four corners of the 10 ft by 10 ft pool. The water sample locations were designated Corner 1 (Northwest Corner), Corner 2 (Northeast Corner), Corner 3 (Southeast Corner), Corner 4 (Southwest Corner), and Center. To establish a

vertical profile within the pool, water samples were collected at two different depths at the Corner 1, Corner 2, and Center locations and three different depths at the Corner 3 and Corner 4 locations. The vertical profile water samples were designated shallow (S), mid-point (M), and deep (D). At the Corner 1, Corner 2, and Center locations, sample depths were approximately two inches below the surface and 18 inches below the surface (or two inches above the bottom of the pool). At the Corner 3 and Corner 4 locations, sample depths were approximately two inches below the surface, ten inches below the surface and 20 inches below the surface (or two inches above the bottom of the pool).

To ensure that samples were collected simultaneously from multiple depths at each sampling location, Teflon sample tubing was mounted to a wooden stand, and the height of the sample tubing was positioned below the top of the water column in the pool. Sample tubing was identified by color-coded labels that indicated the sample location and sample depth for the sampling team. Prior to conducting the Still Water sampling event, the sample tubing for each sampling location was briefly purged with a peristaltic pump to establish a flow pathway and subsequently capped to maintain pressure in the sample tubing lines. Sampling was performed via siphon where each sampling line was filled with water to promote the free flow of water. Each line was cut to the same length in order for the sample purge time (10 seconds) to be the same at each location. Each line was capped between sample times and was removed for purging and sampling. Background water sampling occurred approximately 30 minutes before the controlled release. Post-spill water sampling occurred at approximately 15, 30, 45, 60, 120, 240, 300, and 1440 minutes after the spill.

A total of 96 water samples were collected for field screening. The screening results from the procedure were not reliable and are not included in this report.

A subset of 11of the 96 samples had an additional set of three 40-mL vials, which contained hydrochloric acid (HCl) as a preservative, collected for analysis by the SERAS Analytical Laboratory. Two matrix spike/matrix spike duplicates (MS/MSDs), each consisting of a set of six 40-mL vials with HCl preservative, were collected for quality control analysis by the SERAS Analytical Laboratory. In addition, two field blanks and two trip blanks (both collected at a frequency of one per day) were collected for quality control analysis by the SERAS Analytical Laboratory.

Additional Mobile Monitoring

Mobile air monitoring for VOCs, $\%O_2$, LEL, H_2S and CO were performed utilizing a RAE Systems MultiRAE Pro PGM 6248. Mobile air monitoring for VOCs was also performed using the TVA-1000B. This mobile monitoring was conducted (to the best extent possible) at the same location and time as the benzene monitoring and sampling.

4. Results

Air Monitoring and Tedlar Bag Sampling for Benzene

SERAS prepared the report, *GC/MS Analytical Report, Bakken Crude Release: Worker Health & Safety Pilot Scale Study, Leonardo, New Jersey from March 2015,* which provides the on-site analytical results from the Cold Weather Scenario.

SERAS prepared the report, *GC/MS Analytical Report, Bakken Crude Release: Worker Health & Safety Pilot Scale Study, Hillsborough, New Jersey from August 2016,* which provides the on-site analytical results from the Warm Weather Scenario.

Table 3 contains a comparison of benzene air monitoring and sampling results from the cold and warm weather studies in parts per million by volume (ppmv) from February 11, 2015, June 15, 2016 and June 16, 2016. A comparison of benzene air monitoring and sampling results during the skimmer tests on February 12, 2015 are presented in **Table 4**. The results from **Table** 4 are presented for information purposes only as this scenario was only conducted during the cold weather study.

Benzene air concentrations during the Cold Weather Scenario were below the National Institute for Occupational Safety and Health (NIOSH) Recommended Exposure Limit (REL) of 0.1 ppm after approximately 95 minutes of the spill in the immediate vicinity based on the GC/MS results. While benzene air concentrations during the Warm Weather Scenario were below The NIOSH REL of 0.1 ppm after 240 minutes during the still water scenario and after 180 minutes after the turbulent water scenario in the immediate vicinity based on the GC/MS results.

Benzene air concentrations during the Cold Weather Scenario were below American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Value (TLV) of 0.5 ppm after approximately 45 minutes of the spill in the immediate vicinity based on the GC/MS results. While benzene air concentrations during the Warm Weather Scenario were below The ACGIH TLV of 0.5 ppm after 180 minutes during the still water scenario and after 120 minutes after the turbulent water scenario in the immediate vicinity based on the GC/MS results.

The time difference between the Still Water and the Turbulent Water scenarios support the hypothesis that an active waterway would drive off the benzene (and other volatile organics) more quickly than an undisturbed body of water.

The UltraRAE monitor was used for real-time screening for benzene while the Tedlar bag generate definitive results. The UltraRAE results can also be found in **Table 3** and **Table 4**. These results relate to the comparability of the UltraRAE monitoring results to the Tedlar bag sampling results.

ND (1) - Concentration not detected above 0.50 ppbv detection limit for the GC/MS Analysis

ND (2) - Concentration not detected above 50 ppbv detection limit for the Benzene Separation Tube

(3) - Final Position

ppbv = parts per billion by volume

ASTM Tests 1 and 2 utilized 24 hour weather oil. ASTM Test 3 utilized fresh Bakken Oil Crude.

Charcoal Tube Sampling

As indicated previously charcoal tube sampling was only conducted during the Cold Weather Scenario. The daily time-integrated charcoal tube benzene air sampling results are presented in **Table 5** based on the hours of operation each day of the study. The highest time-integrated concentration of 75.1 parts per billion by volume (ppbv) was observed on the release day at the south mobile bridge location.

The time-integrated charcoal tube benzene air sampling results near the skimmer test are presented in **Table 6**. The highest time integrated concentration of 50.4 ppbv was observed after the third skimmer test with fresh oil on the south side of the north mobile bridge location.

All sampling results were below the National Institute for Occupational Safety and health (NIOSH) REL for benzene of 100 ppbv.

TAGA

During the February 11, 2015 TAGA mobile monitoring the highest instantaneous benzene concentration of 552 ppbv was observed along the TAGA monitoring path aside the western wall of the tank. The highest set of path readings averaged over a mobile monitoring run (one complete set of readings from the round-trip path along the tank) was 100 ppbv. On February 12, 2015, the highest fixed point instantaneous benzene concentration of 1,341 ppbv was observed directly above the skimmer test area. This occurred just after the third ASTM skimmer test following the addition of Bakken Crude Oil to the OHMSETT pool. Prior to the addition of the fresh oil the highest instantaneous benzene concentration was 83 ppbv. During the first two skimmer tests of 24-hour weathered oil, fixed point monitoring showed that all results were below 100 ppbv. During the third skimmer test on fresh oil, all of the monitoring results during the monitoring period were above 500 ppbv.

The report, *Final Analytical TAGA Report, Bakken Crude Release: Worker Health & Safety Pilot Scale Study, Leonardo, New Jersey from May 2015,* was prepared by SERAS and submitted under separate cover.

During the June 14, 2016 TAGA mobile monitoring the highest instantaneous benzene concentration of 1,400 ppbv occurred along TAGA monitoring path #1 located to the southeast of the still water tank approximately 15 minutes after the release of the oil. All TAGA monitoring results for this scenario were below 500 ppbv approximately 150 minutes after the release and below 100 ppbv approximately 240 minutes after the release.

On June 15, 2016 the highest instantaneous benzene concentration of 2,200 ppbv was observed along the TAGA monitoring path #2 located to the southeast of the turbulent tank approximately 30 minutes after the release of the oil. All TAGA monitoring results for this scenario were below 500 ppbv approximately 135 minutes after the release and below 100 ppbv approximately 270 minutes after the release.

The report, *Final Analytical TAGA Report, Bakken Crude Release: Worker Health & Safety Pilot Scale Study, Hillsborough, New Jersey from March 2017,* was prepared by SERAS and submitted under separate cover.

Water Sampling and Analysis

The water samples collected the day of the spill and analyzed by the SERAS Laboratory were all from different locations and different depths. Benzene concentration ranged from 237 micrograms per liter (ug/L) to 315 ug/L on the day of the spill. The two samples collected the day after the spill ranged from 216 ug/L to 218 ug/L. Dissolution of benzene into the water column occurred rapidly as the concentration of benzene in the first sample was 315 ug/L after 25 minutes after the oil was introduced to the tank. The benzene concentration remained above the maximum contaminate level of 5 ug/L throughout the 24-hour period of the study. **Table 7** shows the SERAS Laboratory water sampling results.

Stationary Ambient Air Monitoring

During the Cold Weather Scenario, total VOC concentrations in the ambient air, in the immediate vicinity of the spill (North Deck, East Deck, South Mobile Bridge and West Deck) remained above 0.1 ppm from the beginning of the spill until the next morning based on results from the AreaRAE monitoring. The total VOC results from locations away from the spill perimeter (North Fence line ~250 ft, OHMSETT Office ~190 ft and Southwest Corner of the Deck ~540 feet) were below 0.1 ppm within approximately 6 hours. The data from the AreaRAE located at South Fence line has been excluded as instrument drift rendered the data unreliable.

During the Warm Weather Still Water scenario, total VOC concentrations in the immediate vicinity of the spill (at the east and west locations) remained above 0.1 ppm from the beginning of the spill until the next morning (when they rose to between 1 and 3 ppm) based on results from the AreaRAE monitoring. The total VOC results from locations away from the spill perimeter at locations North Fence line, Entrance to ESTA and North Side Entrance Door were below 0.1 ppm throughout the Still Water scenario. VOC air monitoring results at the East Fence line were below 0.1 ppm approximately 8 hours after the spill. Results from East Fence line Building D were below 0.1 ppm from the beginning of the spill for the first 10 hours. From that time until the conclusion of the monitoring run the next morning, total VOC concentrations ranged from 0.1 ppm to 1.1 ppm.

During the Warm Weather Turbulent Water scenario, total VOC concentrations in the immediate vicinity of the spill (at the east, south and west locations) remained above 0.1 ppm from the beginning of the spill until the next morning (between 0.1 and 3 ppm) based on results from the AreaRAE monitoring. The total VOC results from locations away from the spill perimeter at locations East Fence line, Entrance to ESTA and North Side Entrance Door were below 0.1 ppm throughout the Turbulent Water scenario. The majority of the VOC air monitoring results at the East Fence line and the North Fence line were below 0.1 ppm. There were 12 instantaneous readings collected at these locations ranging from 0.1 to 0.6 ppm over the duration of the monitoring period.

For detailed graphs of the stationary monitoring, please refer to reports *Bakken Crude Oil: Worker Health and Safety Pilot Scale Study from February 2015* and *Bakken Crude Oil: Worker Health and Safety Pilot Scale Study from June 2016* prepared individually by SERAS and submitted under separate cover.

Additional Mobile Monitoring

Table 8 contains the results for the additional air monitoring that was conducted during the Warm Weather scenario. The benzene results are repeated here for comparison.

The NIOSH immediately dangerous to life or health (IDLH) for oxygen is 19.5%. At oxygen concentrations below the NIOSH IDLH supplied air is necessary for the first responder. Oxygen deficient atmospheres of less than 19.5 % were observed immediately adjacent to each spill. During the Still Water condition, three hours passed before the percentage of atmospheric oxygen rose above 19.5 % and for the Turbulent Water condition, two hours passed before oxygen reached 19.5%.

There were large discrepancies between the FID and PID readings with the FID readings higher for VOCs than the PID readings. This was particularly evident during both the Still and Turbulent Water conditions for the first 90 minutes following the spill. The highest VOC reading by the FID occurred 35 minutes after the spill for Still Water condition (7300 ppm) and one minute after the spill for the Turbulent Water condition (9400 ppm).

Total VOC concentrations measured along the perimeter of the tanks on both the PID and FID remained above the benzene NIOSH REL of 0.1 ppm and the ACGIH TLV of 0.5 ppm after nearly 24 hours of the initial release for both the still water and turbulent water scenarios.

5. Discussion of Variability

When the Cold Weather and Warm Weather scenario results are compared there are some notable differences in analytical results. Some of the differences in results are expected, others are likely the result of differences in study methodologies.

- Surface area differences of 6,500 square feet (ft^2) for cold versus 100 ft^2 for warm along with the volume of oil difference causing a difference in the calculated thickness of oil of 0.16 inches of oil for cold versus 1.13 inches for warm. The thinner, larger slick allowed for the benzene to be liberated readily during the Cold Weather scenario. For the Warm Weather scenario, the thickness of the oil layer inhibited the release of benzene into the air from the crude oil.
- During the Cold Weather scenario the wind speeds during the sampling were between 1.7 and 9 miles per hour (MPH). For the Warm Weather scenario the wind speeds during the sampling were between 1.6 and 6.3 MPH. Based on the wind speed and incoming solar radiation atmospheric stability can be calculated. The majority of weather observations during the Cold Weather scenario would fall within slightly unstable atmospheric condition category while the weather observations during the Warm Weather scenario would fall within the unstable to very unstable atmospheric condition categories. The more stable the atmosphere, the more consistent and tighter a pollutant plume would be. The more unstable the atmosphere the more mixing and less consistent a pollutant plume would be. [7]
- There were differences in benzene and VOC sampling heights for the two scenarios. The sampling height for the cold weather operation was approximately 5 to 6 feet above the tank, while for the warm weather operation air monitoring/sampling was performed at approximately 1-foot above tank level.
- The available sampling perimeters were different for the two scenarios and this affected the choice of sampling locations. During the Cold Weather scenario, the sampling area was more wide open, whereas, during the Warm Weather scenario, space was limited.
- A review of photographs indicates that there were differences in the co-location differences for UltraRAE monitoring and Tedlar bag sampling both within a scenario and between the Cold and Warm scenarios.

6. Conclusions

Benzene airborne concentrations dropped more quickly to levels below the ACGIH TLV TWA of 0.5 ppm and the NIOSH REL of 0.1 ppm during the Cold Weather Scenario than the Warm Weather Scenario. These differences are likely the result of the larger surface area and thinner spill thickness for the Cold Weather Scenario providing a quicker pathway for the transfer of benzene to the atmosphere. With regard to the Warm Weather Scenario, the rapid mixing of the surface crude oil in the turbulent water condition relative to the still water condition is the likely explanation of the quicker disappearance of benzene in the turbulent water condition than the still water condition.

In proximity to the crude oil release during a Warm Weather scenario the oxygen level declined to 18.4% and remained at levels below the below the NIOSH IDLH limit of 19.5% for approximately 4 hours. First responders must be in Level B personal protective equipment with full-facepieces and supplied air. The use of real-time monitoring equipment to determine airborne oxygen concentrations is critical for all first

[7] SE Gryning et al, Applied dispersion modelling based on meteorological scaling parameters, Atmospheric Environment, (1987), Vol 21: 1, 79-89.

responders in proximity to the oil spill. The monitoring results should be carefully reviewed before any downgrading of respiratory protection occurs.

7. Items for Further Investigation

- Eliminate differences between study conditions for Cold Weather scenario and Warm Weather scenarios when possible. This effort will strengthen the conclusions drawn from the study results for the two scenarios.
- In an effort to arrive at better agreement in benzene monitoring and collocated sampling results, suggested sampling changes include minimizing the collection devices. One possibility would be to collect a larger sample aliquot over a longer period. Upon collection, bag(s) could first be run by GC/MS followed by screening with monitoring instruments. This would ensure that the same parcel of air is being quantified. Alternatively, collect a larger sample volume (for screening with air monitors) and separate Tedlar bags for GC/MS analysis. This option would minimize the chain of custody documentation requirements and allow for the screening and analysis to occur simultaneously.
- Other readily available real-time benzene specific air monitoring devices could be researched and considered for inclusion in future studies.
- For comparable results between the field monitoring and the laboratory analysis, a benchtop or a Performance Evaluation (PE) Study (Tedlar bag versus field monitoring) using known concentrations of benzene in a similar complex matrix could be performed.
- Investigate additional real-time monitoring equipment for use during oil spill episodes and further characterizing emissions during the first several hours following an oil spill; better equipment may be identified and additional important information on VOC levels and oxygen levels will be gained during the initial time period following the oil spill. Based on the results of the current studies, depleted oxygen levels and elevated VOC levels may pose a real concern for first responders.

Current results indicate that the FID shows significantly higher emission rates than for the PID. This is particularly evident during the initial hours after the spill. This suggests appreciable emissions of VOCs with ionization potentials greater than 10.6 eV may be present and contain gases that cannot be measured by the PID that was used but are measured by the FID. The introduction of Tedlar bag air sampling will provide the important identification and quantities of VOCs that account for the elevated VOC levels as measured by the FID.

ATTACHMENT A - OHMSETT FACILITY, WEATHERING AND RECOVERY OF BAKKEN CRUDE OIL

EXECUTIVE SUMMARY

WEATHERING AND RECOVERY STUDY OF BAKKEN CRUDE OIL FOR THE U.S. E.P.A.

Background:

During the week of 2/9/2015 an evaluation of rheological properties, Volatility (VOC emission rate) and recoverability of Bakken crude oil was performed at the Ohmsett Test Facility. As a relatively new crude oil to the market place which is widely transported, there is an increased risk of spills into the environment. Crude oil spills pose a threat to human health and the environment, quantitative data related to the oil physical properties is needed to define risks.

Response to inland oil spills that threaten waters and sensitive environments is one of the responsibilities of the US Environmental Protection Agency (EPA). In an effort to add to the knowledge base for responding to a discharge of Bakken crude oil, this evaluation focused on multiple factors and conditions that exist from the time of release to a number of days later. Namely, due to known high vapor pressure and volatility the corresponding emissions were measured; and second, due to the low viscosity when fresh evaluate the ability to recover the oil using oleophilic type skimmers.

While significant testing has been performed by different organizations on crude oil produced from the Bakken formation, the testing is generally comprised of standard petroleum characteristic analyses and characterization for proper Department of Transportation (DOT) classification for transportation. The data from these testing programs have provided critical knowledge for classifying and understanding standard properties of the light sweet crude. Questions continue to be raised by the response community and all levels of government as oil releases into the environment through spills, well blowouts, major derailment events, and associated fires have caused damage and the loss of life. The potential for more oil spills is a reality with the increasing volume of oil being moved across the country from the Williston Basin production to the refineries. As of July 2014, the volume of oil from the Williston Basin being shipped by rail on unit trains is approximately 766,000 barrels per day, and the volume transported in pipelines is approximately 432,000 barrels per day (EPR, Inc November 2014).

Little quantitative testing has been performed with this oil with respect oil recovery equipment or various physical and chemical property changes that occur once released into the environment. Information obtained from this test provides some quantitative evaluation of the crude oil relative to spill response considerations. This information will be used to support spill response planning relative to responder safety and effective oil recovery procedures to protect the environment.

Test Objectives:

1. Perform air monitoring (VOC emission rate) to determine health and safety risks to responders.

2. Determine the change in basic physical properties over time due to weathering (density, viscosity and interfacial tension).
3. Determine if weathered and fresh Bakken crude oil is recoverable using an oleophilic type skimmer.

Air Monitoring/Weathering Tests: (Objectives 1 & 2)

Setup:

To meet the objectives of the air monitoring/weathering study, a large defined surface area on the water was required where the Bakken Crude oil was dispensed and contained. The rectangular area provided was 65 feet wide x 100 feet long within the test basin and was formed using the tank walls and containment booms. The 6500 foot^2 area provided a sufficient surface area from where emissions could emanate for air monitoring data. Additionally, the large volume dispensed provided a sufficient volume of oil for subsequent weathered crude mechanical recovery testing. Figure 1 shows the test area with Bakken Crude oil dispensed, the containment booms, and the auxiliary bridge with a skimming barrier.

Figure 1 Bakken Crude oil dispensed

Preparation for air monitoring and all related data collection was performed by the USEPA and US Coast Guard (USCG) teams. Detection and emissions monitoring equipment was positioned around the spill zone. In addition, hand held detection monitors were in use for real-time measurements. Ideally a large volume of oil would be dispensed, approximately 600 to

1000 gallons. The volume to be released on the surface was dependent on real-time readings for the LEL and benzene levels obtained during the process. If threshold readings were reached, the dispensing would halt. In the event that a hazardous condition developed, the remediation procedure was to reduce the oil slick surface area using the auxiliary bridge skimming barrier that was pre-positioned within the test area. The water within the test basin is salt water and the water properties are reported in the lab analysis section of this data summary binder.

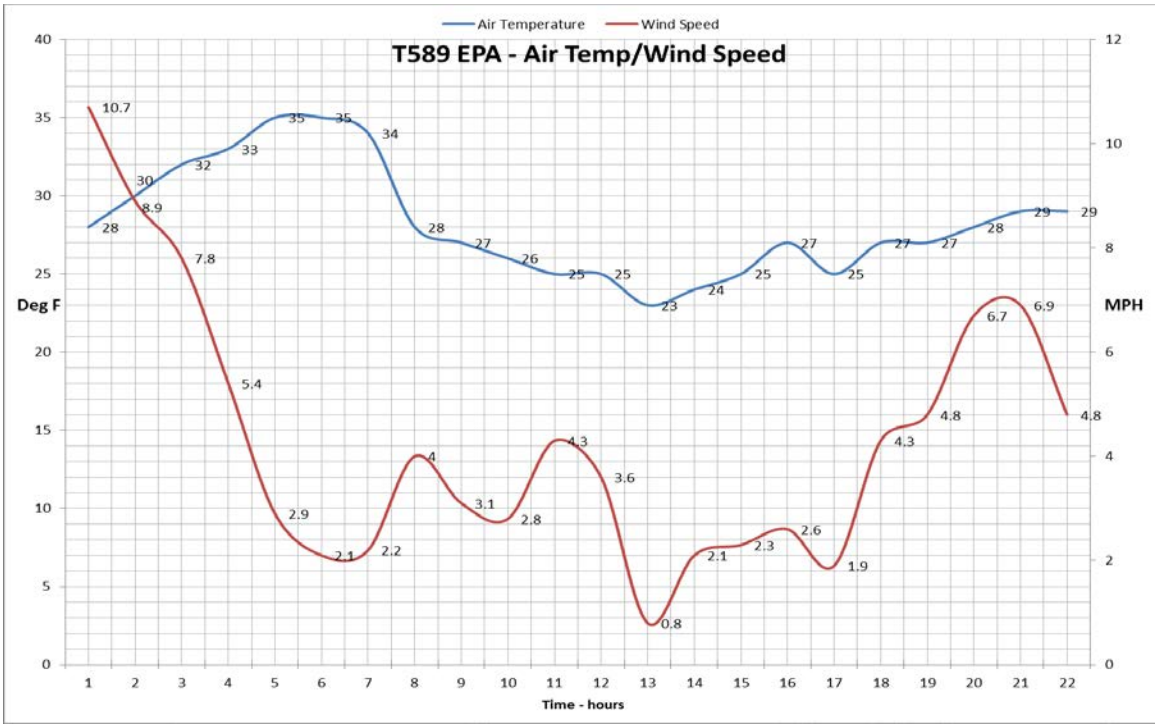
In addition to obtaining air monitoring data, the purpose of this evaluation was to study the rate at which spilled Bakken crude oil weathered in terms of basic oil properties. This was accomplished by obtaining surface samples of the crude oil at timed intervals for analysis in the Ohmsett laboratory. The surface oil sample analysis included viscosity, density, interfacial tension, and bottom solids and water (BS&W).

Procedure:

The air monitoring/weathering test started on 2/1/2015. With all instruments and personnel ready, oil was delivered to the confined area. The crude oil was gravity fed directly into the test area from 330 gallon totes that were elevated on a forklift. A fanning nozzle was employed at the end of a 2-inch hose and was positioned at the water surface. The total amount dispensed was 662 gallons at an average rate of 47 gpm. The resulting volume equated to an average slick thickness of 0.16 inches (4mm) for the 6500 $ft.^2$ area. Volumes were calculated based on soundings obtained from the storage totes.

While continuous air sampling was taking place, Ohmsett technicians obtained surface samples of the oil for laboratory analysis. Samples were obtained at half-hour intervals for the first three hours, and hourly until the conclusion of the work day. The samples are sequentially numbered and identified; for example, as 589-R01 (R-indicating "recovered sample). The Bakken crude oil remained on the test basin surface until the following morning when after 22 hours, a surface sample was obtained and the slick then consolidated into a smaller area using the auxiliary bridge barrier. Once consolidated, an Elastec TDS-118G (grooved drum) skimmer was used to recover the oil into totes.

Once collected, the recovered fluid was allowed to gravity separate and free water was decanted from the bottom of the totes. Final soundings resulted in 448 gallons of the 662 dispensed having been recovered indicating a 32% loss of oil by volume after approximately 22 hours of weathering. During this 22-hour period, the average water temperature was 30.8^0F, average air temperature 28^0F and average wind speed 8 mph. Graph 1 shown below provides wind speed and air temperature readings for the 22-hour period. The recovered oil would later be used for mechanical skimmer recovery testing.



Graph 1 Wind Speed and Air Temperatures during 22 Hours of Weathering.

Additional weathered oil samples were obtained two and five days later. These samples were obtained by dispensing the previously weathered oil into a boomed area after the skimmer testing had concluded. Figure 2 shows the recovery operation at the conclusion of the weathering test.

Figure 2 Oleophilic skimmer recovering oil after weathering period.

Weathered Bakken Crude Oil Results:

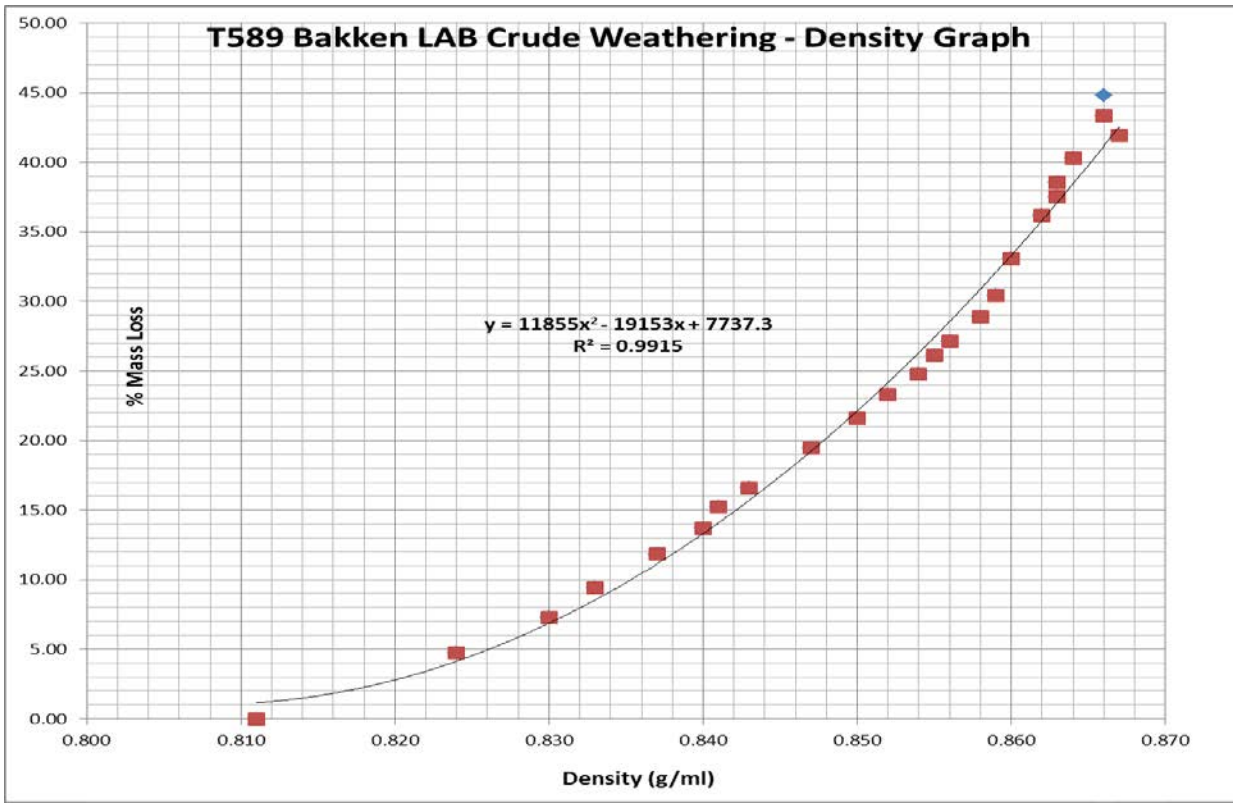
The Bakken crude oil (662 gallons) was completely dispensed into the defined test area at 10:41 am on 2/11/15. Surface samples were obtained at half-hour intervals until 1:10 pm. Two hourly samples were obtained ending at 3:10 pm. The oil remained in the test basin until 8:30 am the following day when sample 589-R09 was obtained. After using the oil for skimmer testing, 60 gallons was reintroduced into a smaller test area for extended weathering. The sample obtained for this oil was identified as 589-R010 and the duration recorded as the total time in use.

The properties measured in the Ohmsett laboratory are presented in a table "USEPA Bakken Crude Oil Spilled Oil Properties Analysis" provided in the "Spreadsheet Data/Results" section of this data summary binder. At 0^0C the viscosities did increase due to weathering from initially 29.7 to 42.9 cPs (at 20^0C 13.4 to 24 cPs). The test basin water temperature during the weathering ranged from 29.7^0F and 30.9^0F. The density consistently increased over time from 0.807 g/ml to 0.865 g/ml. Interfacial tension increased from 17.3 to 20 dynes/cm.

Laboratory Weathered Oil Data:

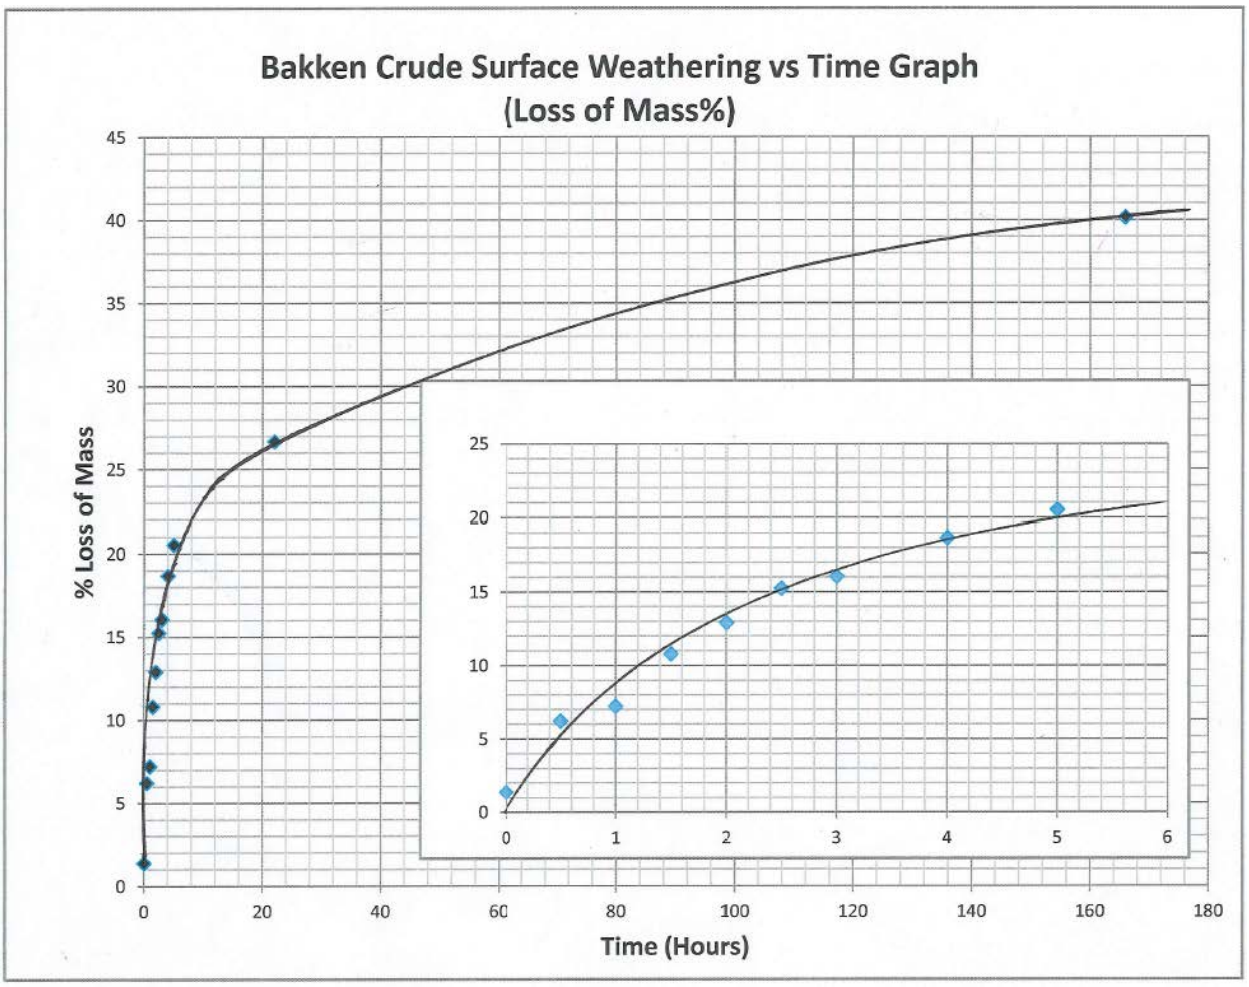
A physical indication of the extent of oil weathering typically sighted is the loss of mass as a function of time. In order to determine the loss of mass directly for the free floating crude oil, it would have been necessary to gather all the oil periodically and somehow weigh it. The scale of this operation is likely to have introduced error due to handling as well as the interruption of the time line. Therefore, the following surrogate method was used as opposed to the direct weighing approach.

A representative sample of the fresh, unaltered Bakken crude oil was weathered in a vented bubbler under controlled conditions in the laboratory. At various time intervals, more closely spaced at the beginning of the experiment, the bubbler was stopped and sealed, and the time, net oil mass, oil density, and temperature recorded. This provided data equating "loss of mass" to oil "density". The results of this effort are presented in the "Spreadsheet Data/Results" section of this binder and "Laboratory Weathering Data" in table form, "% Mass Loss versus Density" and "% Loss of Mass versus Time" (lab time) shown graphically. The "time" during laboratory weathering was recorded as a "sanity check", it is understood that this time has no relationship to the time recorded while weathering the crude oil on the tank surface. However, the laboratory curve of "% Mass Loss" as a function of density change could be used to correlate the extent of weathering on the test basin in terms of "% Mass Loss" given density values and times obtained from surface samples. An equation for the relationship of "% Mass Loss versus Density" has been generated and is shown on the Graph 2 below.



Graph 2 Laboratory % Mass Loss versus Density Curve

Using this equation and substituting the density values measured from the surface samples, yields a corresponding "% Mass Loss value". Time was then reintroduced into the relationship and resulted in the "% Mass Loss versus Time" for weathered Bakken crude oil given the ambient conditions. Graph 3 below is the result of the correlation and is also provided within the "Spreadsheet Data/Results" section of this binder.



Graph 3 %Loss of Mass versus Time from Test Basin Surface Samples

Oil Recovery Testing: (Objective 3)

The primary goal of objective 3 was to determine if the Bakken crude oil is recoverable using an oleophilic type skimmer. Tests were performed in which the recovery rate (RR) and corresponding recovery efficiencies (RE) were quantified while in a slick of weathered Bakken crude oil. The test method followed was ASTM F2709 "Standard Test Method for Determining Nameplate Recovery Rate for Stationary Skimmer Systems". The weathered oil from the emissions testing was collected and used for this test. Additionally, a recovery test was performed using fresh crude in a one inch slick.

Setup/Procedure:

A 10-foot x 10-foot boomed test area (Figure 3) was setup along the west wall of the test basin that provided for three times the footprint area of the skimmer, per ASTM 2709. A preload volume of weathered Bakken crude test oil was added to create the required nominal slick thickness of 3 inches plus an additional amount allowed for system startup to establish steady state operation and hold-up volume in the 2-inch x 50-foot cargo hose.

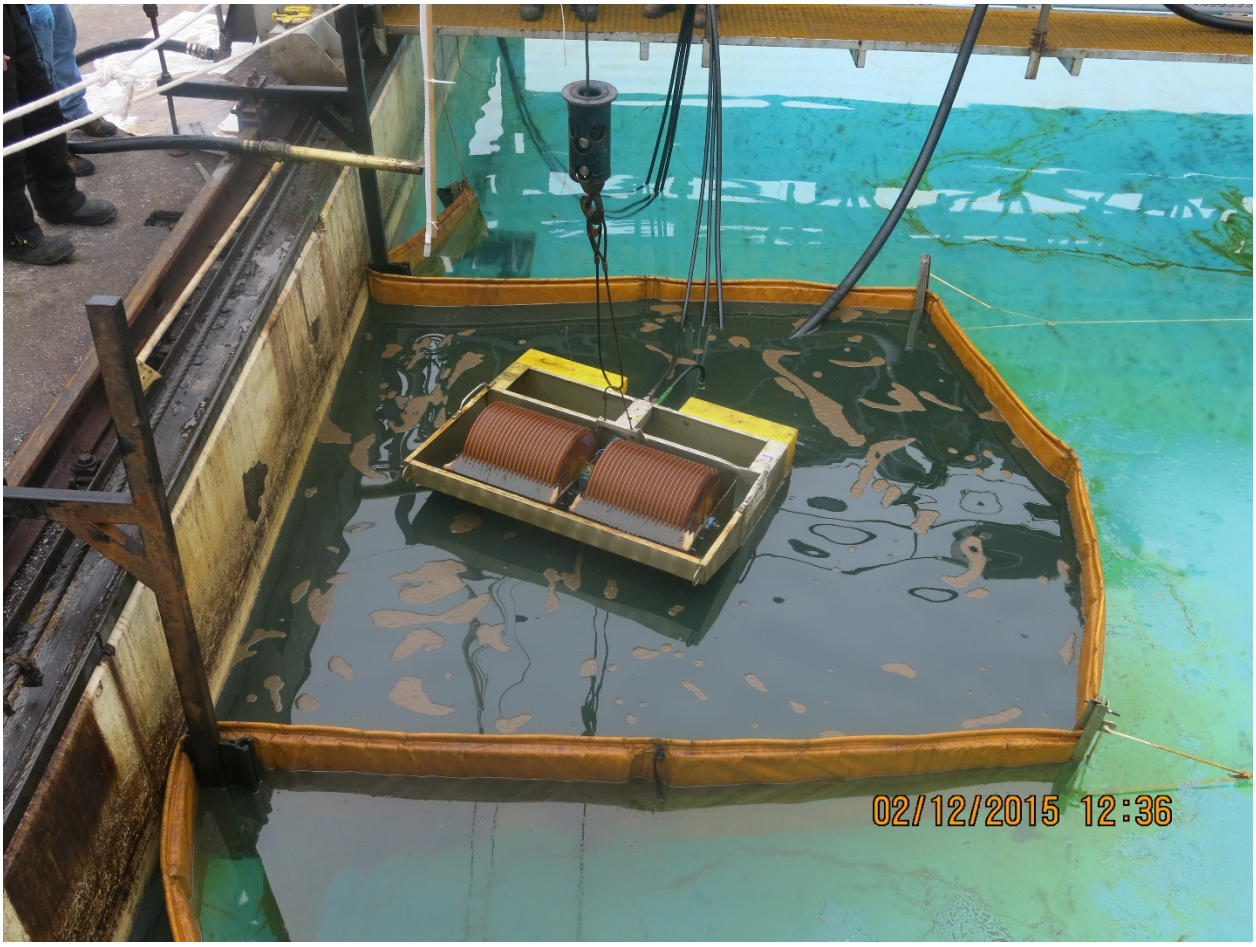


Figure 3 Skimmer Test Area

The 2-inch cargo line discharge outlet was elevated 14 feet above waterline meeting the minimum static head requirement of 3.5 m (11.5 feet) per the ASTM standard. The recovered fluid was directed into compartmented recovery tanks for measurement and sampling purposes.

The skimmer used was an Elastec TDS-118G. It is constructed of marine-grade aluminum and is 53 inches wide, 36 inches long, and uses two 17-inch diameter x 17-inch wide oleophilic grooved drums to recover oil. As the drums rotate through the slick, oil adheres to the surface of the drums and is scraped off by contour conforming scrapers located on the grooved face of the drums and the flat ends. The recovered oil flows into a perimeter trough and continues into a sump where recovered fluid is offloaded with an Elastec E150 transfer pump. An Elastec American Marine D-10 HPU (hydraulic power unit) provided the hydraulic power to the drum motor and the E150 offload pump.

Due to time restraints, preliminary testing was not performed in which multiple operational speeds of the skimmer are investigated to optimize recovery and efficiency. For this study, the operational speed of the skimmer was adjusted to a speed that visually appeared to provide the best performance.

At test start up, the skimmer operator started the power pack and ran at full throttle. The drum speed and pump controls were adjusted to visually achieve the best recovery rate. The system was

allowed to attain steady state operation, establish flow, purge fluid in the cargo line, and collect the holdup volume to a "slop" tank.

Initially, flow was directed to a 'slop' compartment in the recovery tank until the holdup volume was collected; then a three-way valve was swung to divert recovered fluid to a selected recovery compartment where it was timed by the engineer. Recovery continued until 62 gallons, equivalent to 1 inch of slick was recovered and total collection time recorded.

Oleophilic Skimmer Recovery Results:

While recovering weathered Bakken crude oil (drum rotational speed 58 rpm), the skimmer achieved an average recovery rate (RR) of 21.5 gpm with a corresponding recovery efficiency of 97.4%. The actual test oil viscosity (determined at average recovered fluid test temperature of 36.3^0F) was 48 cPs.

The primary objective of this test was to determine if the fresh Bakken crude oil was recoverable using an oleophilic skimmer; a "go"- "no go" event. The oil was found to be recoverable albeit at a lower rate than the weathered oil. At 52 rpm in a 1-inch slick, the skimmer RR was 5.6 gpm. The skimmer performance data sheet is provided below and in the results section in this data summary binder.

BAKKEN CRUDE OIL RECOVERY TEST USING AN ELASTEC TDS 118G SKIMMER

Test #	Test Oil	Collection Time	Drum Spd	Depth Recovery Tank (initial)	Depth Recovery Tank (after decant)	Recovery Tank Fluid Volume (Gross)	Fluid Collect Rate	% BS&W Recovery Tank	Initial BS&W in Preload	Volume of Oil Collected to Recovery Tank	RE Oil Recovery Efficiency	RR Oil Recovery Rate
		(min)	(rpm)	(inches)	(inches)	(gal)	(gpm)	(%)	(%)	(gal)	(%)	(gpm)
1	Weathered Bakken Crude	3.01	58.0	12.00	12.00	69.96	23.24	2.80%	0.00%	68.00	97.20	22.59
2	Weathered Bakken Crude	3.60	58.0	12.75	12.75	74.33	20.65	2.40%	0.00%	72.55	97.60	20.15
Test 1 & 2 description -- stationary skimmer recovery test, rates determined while recovering a deminishing slick from 3 to 2 inches.												
3	Fresh Bakken Crude	3.11	52.0	3.00	3.00	17.49	5.62	0.00%	0.00%	17.49	100.00	5.62
Test 3 description -- stationary skimmer recovery test, rates determined while recovering a deminishing slick from 1 to 0.7 inches. Note RE was not quantified.												

Table 1. Oleophilic Skimmer Recovery Rates of Bakken Crude Oil

Although not a directly comparable recovery rate due to the difference in oil type and viscosity, the following information is offered. When testing as per the ASTM method using the same skimmer system and recovering an Ohmsett stock oil (comparable to a refined lube oil; approximate viscosity 180 cPs), the skimmer achieved an approximate 100 gpm RR.

Within this data binder and on the digital thumb drive included are supporting documentation and include the engineer daily test logs, laboratory analysis of oil and water properties, performance calculations, manually recorded logs, video, and still photos.

INITIAL ACTIONS

_____ Determine On-Scene Coordinator Jurisdiction in accordance with Area Contingency Plan
☐ Coast Guard - Coastal ☐ EPA – Inland

_____ Issue Appropriate Broadcast (if applicable)

_____ Initiate CIC (if applicable)

_____ Ensure NRC is notified

_____ Collect and distribute information from all LE databases (if applicable)

_____ Make initial notifications IAW the briefing matrix

_____ Establish safety/security zone as appropriate

_____ Open MISLE case

PLANNING

_____ In accord with Duty PR, classify oil discharge as: **Inland:** ☐ **Minor** ☐ **Medium** ☐ **Major**
Coastal: ☐ **Minor** ☐ **Medium** ☐ **Major**

_____ Receive or develop response plan

_____ Review and update Command Center RM IAW GAR 2.0 worksheet, document in MISLE

_____ Make notifications IAW the briefing matrix

_____ Brief assets. Discuss mission objectives and risks/hazards identified using PEACE model

OPERATIONAL EXECUTION

_____ Dispatch appropriate asset (if applicable)

_____ Receive RM hazards and mitigation with Risk vs Gain from all assets

_____ Brief situation, response plan and RM IAW briefing matrix

_____ Actively monitor case, review/update RM as situation evolves

CONCLUSION

_____ Make notifications IAW briefing matrix

_____ Release all assets (if applicable)

Acknowledgement

On behalf of the entire Committee, we are very pleased to submit the *Delaware River and Bay Oil Spill Advisory Committee Report, 2010*.

As a Committee we were charged to "provide advice, recommendations, and a ranking of priorities for measures to improve the prevention and response to future oil spills in the Delaware River and Delaware Bay" and to present a report detailing those recommendations and priorities to the Commandant of the U.S. Coast Guard, the Governors of the States of New Jersey, Pennsylvania, and Delaware, the U.S. Senate Committee on Commerce, Science, and Transportation, and the U.S. House of Representatives Committee on Transportation and Infrastructure. This report reflects the conclusions as agreed upon by the Committee members through majority vote.

On behalf of the entire Committee, we are thankful for the opportunity to support this effort. Over the past two years. Committee members have worked long and hard to conduct the extensive review and discussions that made this report possible. Committee members contributed countless hours researching, conferring and debating the issues, meeting tight deadlines, providing insight and education to one another, and unselfishly working to develop a consensus report. Thus, we would like to thank the Committee members who were active in this process for their outstanding professionalism, their knowledgeable and highly productive attitude, and their hard work to advance the state of spill prevention, response, and recovery in the Delaware River and Bay.

Additionally, special thanks goes to those members of the public, the governmental agencies, and the oil spill professionals and community who attended the meetings and contributed to subcommittee education sessions and discussions. Their efforts greatly assisted in the Committee's understanding of various topics.

It is also important to emphasize that this Committee and the report could not have been completed without the support of all U.S. Coast Guard Sector Delaware Bay personnel. CAPT Meredith Austin, CAPT David Scott, LCDR Nakeisha Hills and Mr. Gerald Conrad assisted throughout the entire process.

Thank you for the opportunity to assist in advancing oil spill prevention, response, and recovery in the Delaware River and Bay and for the chance to serve as the Chair and Vice Chair for such a remarkable group.

Sincerely,

CAPT Michael Linton, Chair

Edward T. Doyle, Jr., PhD, Vice Chair

Executive Summary - Delaware River and Bay Oil Spill Advisory Committee Report

The Delaware River is one of the highest volume oil ports in the United States and a critical environmental habitat. Therefore, minimizing disruptions in normal port operations and throughout the Delaware Valley estuary due to oil spills is a priority for the entire region. Since 1974 there have been 27 significant oil spill events on the Delaware River (significance being defined by the amount spilled, level of response, or the notoriety of the event). In ten of those events, more than 100,000 gallons of oil were spilled.

The Committee launched its efforts by developing an oil spill history for the River and Bay area, and members were somewhat surprised to discover how difficult it was to gather consistently accurate information on spills into the River or Bay. This was mostly due to the fact that there is no single depository of such information that is consistently managed and kept up to date. However, the history which members were able to piece together clearly shows that operational, vessel vetting, and vigilance issues, along with weather-related and navigational obstruction issues, have contributed to the occurrence these spills.

Overall, the Committee believes that many port stakeholders can within their scope of responsibility make individual process that will benefit the general spill prevention and response mission. The Committee's findings are detailed in the Recommendations section of this report. Although many of the recommendations will require congressional action, others can be handled by the local Area Committee, the States of Delaware, New Jersey, and Pennsylvania and the Mariners' Advisory Committee.

Congressional action will be needed for two main areas:

1) Legislation to allow the Captain of the Port greater authority for directing vessels in need of a place of refuge, and
2) Legislation to enable the Oil Pollution Liability Trust Fund or another mechanism to provide funding for the Area Committee to enhance its role and responsibilities in the prevention, preparedness, response, and recovery issues outlined in various recommendations.

There was much discussion of funding, and it is accurate to say the Committee would rather not mention money. However, it is a reality that must be addressed. Today, port security and counter terrorism issues command a lot of stakeholder attention, and rightfully so. But these issues also are accompanied by funding mechanisms to implement identified and needed prevention, response, and recovery measures. However, oil spill issues do not have a funding mechanism to help advance the identified preparedness needs, i.e., updating booming strategies, submerged oil research, periodic updates of Environmental Sensitivity Index (ESI) maps, establishing and

maintaining port-specific oil spill web sites, and maintaining a Geographic Information System (GIS) Spill Management Database.

Congressional funding also is needed to support the submerged and floating debris missions recommended for the port, to support Department of the Interior and National Oceanographic Atmospheric Administration (NOAA) updates to ESI mapping, to support reauthorization and maintenance of the Natural Resource Damage Assessment (NRDA) Type A computer models, and to increase the cap on damages that are recoverable after small spills to $1 million to reflect current restoration costs.

Area Committee action will be required for a variety of issues. The Area Committee is a standing Oil Pollution Act (OPA '90) group in Sector Delaware Bay whose primary role is preparedness and planning. The Area Committee is made up of various stakeholders including the States of Delaware, New Jersey, and Pennsylvania.

The DRBOSAC recommends enhancing the role of the Area Committee to encourage new active committee membership and funding of the committee for program development in the following areas:

- Submerged oil research, including both detection and recovery,
- Periodic updates of Environmental Sensitivity Index (ESI) maps,
- Establishing and maintaining national and port-specific oil spill web sites,
- A Geographic Information System (GIS) Spill Management Database,
- Protective and preventative booming strategies,
- Information gathering and identification of restoration needs projects,
- A spill of opportunity testing policy,
- Enhancement and maintenance of the Physical Oceanography Real-Time System (PORTS®),
- Collecting, housing, and maintaining oil spill information, and
- The use of volunteers during an oil spill.

The Area Committee, with proper funding and active leadership, can dramatically improve and/or provide the necessary guidance for improvements in these areas. Moreover, it can fill the gap that historically the industry-funded Delaware Bay and River Cooperative (DBRC) has provided, such as the booming of sensitive areas, revising booming locations, and developing booming strategies. With the recent closing of two local refineries and another's future reported to be in question, the DRBOSAC is uncomfortable that the industry co-op's funding in these areas will continue at an adequate level.

In addition, the Area Committee, with support from the states of Pennsylvania, New Jersey and Delaware, should prioritize the sensitive areas in the Area Contingency Plan and provide guidance for the capabilities and timeliness of response required.

State action should focus on reviewing the effectiveness and suitability of protective (pre-booming) of docked vessels and on strategies around pre-cleaning beaches and shoreline in order to minimize the amount of debris which could become contaminated in a spill area. These actions would reduce responder time, disposal needs, and cost in general.

The U.S. Coast Guard in consultation with the Area Committee, should look at the guidelines used for review of Facilities Response Plans required by 33 CFR Part 154. In addition, USCG Headquarters should strengthen the language of 33 CFR 155.1030 (h) so that the Tank Vessel Response Plans and the geographic appendices address the requirements of the Area Contingency Plans (ACP) for protecting fish and wildlife and sensitive environments.

The Mariners' Advisory Committee for the Bay and River Delaware (MAC) should spearhead discussions with the U.S. Army Corps of Engineers and USCG Sector Delaware Bay regarding reinforcing the responsibilities for reporting materials or equipment lost overboard or found during surveys and should evaluate the information exchange necessary among a much wider population of port users. It appears that the *Athos I* incident was caused by submerged debris which was unknown to several key parties. Routine information exchange among a much larger group of port users/mariners may significantly preclude incidents like this re-occurring. It would seem reasonable that the Mariners' Advisory Committee would want to be at the center of these discussions and to help find a process that will work for all parties involved.

Delaware River and Bay Oil Spill Advisory Committee – Overview

Purpose and Description of Duties

The DRBOSAC's Purpose

The purpose of the Delaware River and Bay Oil Spill Advisory Committee (DRBOSAC), as stated in its charter, is to "provide advice, recommendations, and a ranking of priorities for measures to improve the prevention and response to future oil spills in the Delaware River and Delaware Bay". Within 24 months of their appointment the members of the DRBOSAC are to present a report detailing those recommendations and priorities to the Commandant of the U.S. Coast Guard, the Governors of the States of New Jersey, Pennsylvania, and Delaware, the U.S. Senate Committee on Commerce, Science, and Transportation, and the U.S. House of Representatives Committee on Transportation and Infrastructure. This report will reflect only those conclusions as agreed upon by the Committee members through majority vote, and will not in any way be directed by the Coast Guard.

Overview of Membership

The DRBOSAC originally consisted of 27 voting members who have particular expertise, knowledge, and experience regarding the transportation, equipment, and techniques that are used to ship cargo and navigate vessels in the Delaware River and Delaware Bay, as well as those representing environmental and oil spill response organizations, fishing interests, academia, and the private sector. There are also five non-voting members who represent federal agencies and the state agencies of New Jersey, Pennsylvania, and Delaware that have an interest in oil spill prevention. The members of the DRBOSAC are appointed by the Commandant of the Coast Guard and approved by the Secretary of the U.S. Department of Homeland Security.

If, for any reason, a designated member is either unable to continue service on the Committee, or becomes a non-participant, the Commandant of the Coast Guard will appoint an alternate member to serve for the remainder of the absent member's term.

Membership on the DRBOSAC's subcommittee(s), if established, is open to the public; however, the chair of the subcommittee must be a current member of the DRBOSAC.

Meetings

The DRBOSAC is anticipated to meet in Philadelphia, PA, at least twice throughout the course its 18-month operational period with the first meeting being administrative in nature. The number of meetings held and the establishment of subcommittees are to be determined by the needs of the Committee.

Objectives and Scope

The DRBOSAC shall provide advice, recommendations and a ranking of priorities for measures to improve the prevention of and response to future oil spills in the Delaware River and Delaware Bay.

Method of Operation

The initial meeting of the Delaware River and Bay Oil Spill Advisory Committee took place on December 17, 2008. The meeting agenda included:

- A welcome and opening remarks from the then-Commanding Officer, Sector Delaware Bay, Captain David Scott,
- Introduction and swearing in of Committee members,
- Federal Advisory Committee Act and new member orientation by Mrs. Georgia Abraham, Committee Management Office, Department of Homeland Security,
- Special government employee recognition and certificates, Melanee Libby, USCG Headquarters,
- Chair and Vice-Chair elections,
- An oil spill response presentation,
- Establishment and purpose of subcommittees,
- Closing remarks.

The organizational meeting was lead by LCDR Sampson Stevens, LCDR Nakeisha Hills and Mr. Gerald Conrad, Sector Delaware Bay.

The Committee elected Captain Michael Linton, President of the Pilots Association of the Bay & River Delaware as Chair and Edward T. Doyle, Jr. PhD, Chair of Delaware County Local Emergency Planning Committee as Vice-Chair.

The Committee originally agreed to tentatively meet on a bi-monthly basis. The meeting schedule was adjusted in May 2009 to add an additional Committee meeting for September 2009 to accommodate a field trip to Lewes, DE, to board the Delaware Bay and River Cooperative (DBRC) vessel, *DELRIVER,* for an equipment and capabilities demonstration. All meetings were held at Sector Delaware Bay, the John Heinz Wildlife Refuge or the Marcus Hook, PA, Community Center. The schedule is immediately following.

Meeting Schedule 2008
December 17, 2008

Meeting Schedule 2009
Wednesday, January 21
Wednesday, March 18
Wednesday, May 20
Wednesday, June 17
Wednesday, August 19
Wednesday, September 9
Wednesday, October 21
Wednesday, November 18

Meeting Schedule 2010

Wednesday, January 20
Wednesday, February 17
Wednesday, March 17
Wednesday, April 7
Wednesday, April 28
Thursday, December 16

Typical Committee meetings were two or three hours in length generally beginning at 10:00 am and completing by 1:00 pm. Meeting agendas were posted on the Coast Guard web site Homeport and/or sent to members and non-members by email. Typically, an agenda included:

- Administrative items and updates
- Guest speakers or Informational Presentations
- Subcommittee Reports
- General Items for Discussion
- Public Comments

Meetings were open to the public and the public was given an opportunity during meetings to comment or make a request to make a presentation to the Committee or a subcommittee. In addition, some other public persons were asked to take part in subcommittee meetings because of their request to do so or because of their particular expertise, background, or knowledge that could benefit the subcommittee. These individuals were not part of the voting membership of the Committee or subcommittee and were strictly information resources.

Committee Membership

Vignuli, Frank	voting	Director Operations, Diamond State Port Corporation
Balzano, Joseph	voting	Executive Director, South Jersey Port Corporation
Walsh, James	voting	Director Operations, Philadelphia Regional Port Authority
Iuliucci, Fredrick	voting	General Manager , The Vane Brothers Co.
Gazzola, John, CAPT	voting	Vice-President, General Manager, Moran Towing of PA
Schuck, Gregory	voting	Chester Port Manager, Independent Container Line
Merbach, Kurt	voting	Safety Manager , Valero Refining Co.
Kelly, William	voting	Fire & Emergency Manager, Sunoco NE Refineries
Linton, Michael, CAPT	voting	President, Pilots Association of Bay & River Delaware, DRBOSAC Chair
Cuff, John, CAPT	voting	River Pilot, Pilots Association of Bay & River Delaware

Butler, Boise	voting	President, International Longshoreman's Association, Local 1291
Flimlin, George	voting	Marine Extension Agent, East Coast Grower's Association
Van Rossum, Maya	voting	Executive Director, The Delaware River Keeper Network
Maxwell-Doyle, Martha	voting	Deputy Director, Barnegat Bay National Estuary Program
VanDusen, William	voting	Manager, Merck & Co. (Representing Recreational Fishing Alliance)
Bushek, David, Dr.	voting	Asst. Professor., Rutgers Institute of Marine and Coastal Sciences, Haskin Shellfish Research Lab
Kreeger, Danielle, Dr.	voting	Asst. Professor, Biosciences and Biotechnology, Drexel University
Mosley, James	voting	Director of Public Safety, City of Wilmington, DE
O'Neal, Marilyn	voting	Interim Chair Sussex County, DE. Local Emergency Planning Committee
Clark, Leonard	voting	Deputy County Emergency Management Coordinator, Gloucester County, NJ
Barber, Vince	voting	Sr. Environmental Specialist, Hazardous Substance, Camden County, NJ, Department of Health
Doyle, Edward, Dr.	voting	Chair, Delaware County, PA, Local Emergency Planning Council, DRBOSAC Vice-Chair
Johnson, Eugene	voting	President, Delaware Bay and River Cooperative
Roales, Judith	voting	Retired Journalist (Representing General Public)
Mulvenna, Kathleen	non-voting	Emergency Manager, U.S. Army Corps. of Engineers, Philadelphia
Anderson Sr., Bennett	non-voting	Watershed Assessment Branch, Division of Water Resource, DE Department of Natural Resources and Environmental Control
Bauer, Robert	non-voting	Water Quality Spec. Supervisor, PA Department of Environmental Protection
Levine, Edward	non-voting	Scientific Support Coordinator, NOAA, Office of Response
Van Fossen, Robert	non-voting	Assistant Director Emergency Management, NJ Department of Environmental Protection

Yagecic, John	non-voting	Supervisor, Delaware River Basin Commission, Standard Assessment Section

Subcommittees

At the inaugural meeting Committee members were asked to sign up for a specific subcommittee assignment. Although all Committee members were allowed to attend and participate in multiple subcommittees, initial assignments were needed to ensure a mixture of expertise, interest, and discussion of possible concerns and issues. All Committee members volunteered for a primary subcommittee assignment, and some opted to sign on to other subcommittees because of interest or to monitor other subcommittee work and discussions.

Originally, the Committee established four subcommittees – Prevention, Response, Recovery, and Mitigation. Each subcommittee established a lead person and a mission statement for its work which followed general guidance provided by the Committee:

Prevention Subcommittee
This subcommittee will cover topics relative to planning for and prevention of oil spills to the Delaware River and Bay including but not limited to Port Community preparedness, planning activities, response plan fitness and area of coverage, navigation, OPA 90 requirements, new technologies, governmental/industry commitment, and port management issues along with the encouraging aspects of prevention activities.

Response Subcommittee
This subcommittee will cover topics related to the initial response to any and all oil spills in the Delaware River and Bay including but not limited to response capabilities, equipment inventories, equipment availability and fitness, regional support, volunteer issues and solutions, coverage of Average Most Probable Discharge (AMPD), crude oil typing and tracking, safety, and the positive aspects of response within the Sector along with potential recommendations.

Recovery Subcommittee
This subcommittee will cover topics related to the ability to recover from a spill to the Delaware River and Bay, including but not limited to application of advanced technologies, an inventory of recovery issues, preparation and research relative to recovery planning, recommendations for planning strategies, funding recommendations for recovery planning, plan implementation, and securing needed resources.

Mitigation Subcommittee
This subcommittee will cover topics related to the ability among Delaware River and Bay stakeholders to mitigate or lessen the impact of an oil spill on the environment, the area economy, and the area in general, including but not limited to the safe refuge for a stricken vessel, waterway management, new technologies, state and other governmental agency and responsible party activities, salvage, wildlife rehabilitation, special operations, and booming strategies.

After initial subcommittee meetings it became apparent that the Recovery and Mitigation subcommittees were following similar paths and had interest in similar issues so it was

decided at the March 2009 meeting to merge the subcommittees into one – the Mitigation-Recovery Subcommittee.

Report Timeline

As stated earlier, the Delaware River and Bay Oil Spill Advisory Committee (DRBOSAC) originally was chartered in October 2007; however, it was November 2007 before the Federal Register Notice establishing the DRBOSAC and requesting members was published. Solicitation for members ended in late January 2008 with more than sixty people willing to serve. The Commandant of the Coast Guard completed vetting and appointing 27 voting and six non-voting members in October 2008, and the first meeting was held on December 17, 2008, more than a year into the 18-month timeframe provided in the charter.

Although the window for work was greatly reduced, the committee worked diligently to review and discuss the issues surrounding oil spills in the Delaware River and Bay. To further complicate the Committee's efforts, in October 2009 official work was suspended because the DRBOSAC's charter expired. The new charter had to be reviewed and renewed by the new administration. However, to the credit of all Committee members, the subcommittees continued their work. Although Committee efforts were hampered by long governmental administrative delays, the Committee completed its work as outlined in both the original and subsequent charters.

The Committee conducted its final meeting on Thursday, December 16, 2010, at Sector Delaware Bay. All Committee members were notified of the meeting and 17 voting members were present representing a quorum of the 24 voting members who were still members of the Committee. The final vote was unanimous to accept the final report with minor changes to emphasize funding for oil spill preparation, response, planning and mitigation efforts in the Delaware River and Bay and to outline the reason for the report being completed in December 2010 rather than within the18 months of the original charter.

Committee Charters

As discussed in the previous paragraphs, delays in start up of the Committee and the charge of administrations resulted in two charters for the Delaware River and Bay Oil Spill Advisory Committee. Both the October 2007 and the December 2010 charters are found in Appendix A
.

Delaware River and Bay Oil Spill Advisory Committee: Recommendations

Lessons Learned - Oil Spill History (R-1)

Recommendation: Information relative to oil spills should be housed with the Area Committee. This information should be kept current and include lessons learned.

Since 1974 there have been 27 significant oil spill events on the Delaware River (significance being defined by the amount spilled, level of response, or the notoriety of the event). Ten of those exceeded 100,000 gallons of oil spilled. A matrix of these spills in included as an appendix to this report.

The Delaware River is a high volume oil port. However, in attempting to develop an oil spill history for the river and bay area, the Committee was somewhat surprised to discover how difficult it was to gather consistently accurate information on spills to the river or bay. The difficulty was due primarily to the fact that there is no single depository of such information.[1]

The Committee utilized the information gathered to reflect on the varying causes of spills, to establish a point of reference on the occurrence and magnitude of spills, and to determine if there were common causes or contributing factors.

The following list demonstrates the types of information gathered:
January 1975: The *Corinthos*, a 754-foot crude oil tanker was offloading 315,000 barrels of Algerian crude oil at the BP Refinery terminal at Marcus Hook, PA, when it was struck by the *Edgar M. Queeny* which was maneuvering away from the dock at the Monsanto Chemical Plant across the river. An explosion and fire resulted and twenty six persons aboard the *Corinthos* lost their lives. Inspections of the *Queeny* for four years before the incident had shown that the stern engine had a damaged turbine and was only able to drive the ship at 50% of its rated power.

March 1986: The *Intermar Alliance*, a crude oil tanker carrying some 500,000 barrels of Ninian crude, lost steerage while striking the dock at the BP refinery in Marcus Hook. The vessel's #1 port tank sustained a 30-foot-long gash, spilling 189,000 gallons of oil into the river.

November 1989: The Chevron *World Radiance* was transferring oil at the Chevron Hog Island facility when severe weather struck. Shortly after the vessel began transfer operations, the National Weather Service had issued a Severe Thunderstorm Warning for the area. Winds of 40 knots were experienced, and the *World Radiance's* mooring lines failed; the vessel was pushed away from the pier; and 4,200 gallons of oil spilled into the river.

[1] Since the time when the DRBOSAC held their initial meetings, the Coast Guard posted on its HomePort Website an Oil Spill Compendium. The Compendium contains pollution related data and graphics from 1969 to 2008. See http://homeport.uscg.mil> Investigations – Marine Casualty/Pollution Investigations – Oil Spill Compendium 1969 to 2008.

July 1995: 56,000 gallons of West African Rabbi crude oil spilled into the river when the tanker *Jahre Spray* ruptured a transfer hose and manifold due to strong winds during transfer operations at the Coastal Oil Eagle Point terminal on the river at West Deptford, NJ.

November 26, 2004: The *Athos I*, coming into port, struck three submerged objects. As a result 265,000 gallons of heavy crude oil were released into the Delaware River affecting 115 miles of river and 280 miles of shoreline as well as fish, shellfish, and wildlife, including an estimated 16,500 birds. On January 20, 2006, the U.S. Coast Guard released its report on the *Athos I* oil spill. The report titled "Investigation into the Striking of Submerged Objects by the Tank Vessel *Athos I* in the Delaware River on November 26, 2004, with a Major Discharge of Oil" found, among other things:

- *"If Athos I had a double-bottom in place, the marine casualty would probably still have occurred, but it is very probable that the cargo tanks would not have been penetrated, thus avoiding a major oil spill. Evidence indicates the anchor penetrated the bottom of the hull on the Athos I a maximum of 18". The minimum void space in a double bottom as required under OPA 90 for a vessel of this design would have been 6'."*
- *"During the past year, 38 vessels had drafts greater than 35' (Athos I's draft was 36.5'). Investigators then compared the time of arrival with regards to the tidal stage (1 ½ hrs past slack tide with a flood current) for the Athos I to the other vessels and found that all other 38 (sic) vessels had arrived at a later tidal stage."*

Clearly, operational, vessel vetting, and vigilance issues, along with weather-related and navigational obstruction issues, have contributed to the circumstances surrounding spills in the river and bay. The Area Committee and the Maritime Advisory Committee should review and make recommendations relative to transit issues—requirements for when to transit and the circumstance for transit, weather advisories, and mariner notifications. Among the questions that should be addressed are the following:

- How are vessels/mariners advised of potential adverse weather conditions that should cause operations to cease?
- What effect does speed of a passing ship and its suction/surge have on tankers moored alongside docks?
- What are the basic guidelines for vessel vetting?
- Who should lead an outreach effort to restate the rules and requirements for mariners regarding notifying the USCG of navigational hazards?

Place of Refuge (R-2)

Recommendation: Congress should consider legislation that would give the Captain of the Port greater authority for directing vessels in need of a place of refuge. The Sector Delaware Bay Area and Maritime Committees jointly should develop a Place of Refuge Guide for the Sector Delaware Bay Area. Funding for technical assistance should be provided for this effort. The local port authorities and waterfront facilities must be part of this effort, and ideally could identify and maintain a facility as a Place of Refuge in the Port.

A place of refuge is a location to which a vessel needing assistance can be moved temporarily and where actions then can be taken to stabilize the vessel in order to protect human life, sensitive natural and cultural resources, historic properties, national defense, security, economic interests, and critical infrastructure, and to reduce or eliminate a hazard to navigation. For example, a place of refuge could be used during an actual release or threatened release of oil or hazardous material from a tank vessel. It could also be used for any vessel as the result of a threatened or actual terrorist attack.

There is no simple solution to bringing a stricken vessel into port. However, there are tools available from the Commandant of the Coast Guard, the National Response Team, and the International Maritime Organization that can be used by decision makers to deal with safe refuge requests. The Port of Houston/Galveston has developed a comprehensive Harbor of Refuge Plan that could be used as a template for any port.

There are two safe refuge circumstances that the Response Subcommittee considered. The first is when the vessel in need of assistance may be destined for some other port but requests safe refuge within Sector Delaware Bay's Area of Responsibility (AOR). The second circumstance is when a vessel traveling to or from a port on the Delaware River encounters a problem that requires actions to be taken to stabilize the vessel. In these circumstances, the Captain of the Port (COTP) has the authority to order vessels into and out of port or to an anchorage. However, the COTP does not have the authority to order a waterfront facility to accept a stricken vessel. This limits the options for the COTP. Additionally, there is no waterfront facility within the port that is "set aside" and designated as a "place of refuge facility" that will accept a stricken vessel. All available waterfront facilities are conducting business, and a stricken vessel moored to any of the facilities would disrupt that facility's operations. The issue of place of refuge is one that concerns the entire port community (federal, state, and local governments, port administrations, and private industry), not just the COTP.

There are several actions that should be pursued in addressing the place of refuge problem:

- Congress should pass legislation to give the Captain of the Port authority to direct a vessel to a waterfront facility which would work in coordination with state agencies when public safety or resources are threatened. The legislation should include at least the following:

  - Compensation to the facility for use by the vessel,
  - Responder immunity from claims brought by third parties and the vessel for losses allegedly caused by the facility during the vessel's usage,
  - A dedicated source of funding to provide the required compensation, and
  - An administrative process to promptly adjudicated claims for compensation.

- Request funding for a "Places of Refuge Guide for the Sector Delaware Bay Area". This guide should use the "Harbors of Safe Refuge Guide for the Houston-Galveston Area" as a model and should be developed with broad public participation of Delaware Bay area communities as well as all state and federal agencies with responsibilities for public safety and resources. Both the Sector Delaware Bay Area Committee and Maritime Security Committee need to be involved in this effort and will require strong leadership from the COTP.

- Recommend that local port authorities and waterfront facilities work together to identify and maintain a facility -- not located within sensitive habitats -- that is continuously available as a place of refuge facility.

- Pre-identify and establish a core group of personnel who will complete the Places of Refuge Risk Assessment Job Aid within Commandant Instruction 16451.9. This group can be modeled after the Maritime Transportation System Recovery Unit.

Enhance the Role and Responsibilities of the Area Committee and Provide the Committee with Funding for Oil Spill Prevention, Response, and Recovery Programs (R-3)

Recommendation: Consider enhancing the role of the Area Committee and expanding membership in the Area Committee to include all facets of the port community, and provide a funding mechanism through the Oil Pollution Liability Trust Fund to enable the Area Committee to enhance prevention, response, and recovery programs and activities.

Sector Delaware Bay is susceptible to oil spills as outlined in the Committee's spill history research (recommendation R-1). The Sector, however, does enjoy a cooperative environment among local industry including six major refineries, response organizations such as Delaware Bay and River Cooperative (DBRC) and Tri-state Bird Rescue and Research, experienced and professional mariners such as the Pilots Association of the Bay & River Delaware, state environmental agencies from the three states, and watch groups such as the Delaware River Keepers. This provides a positive climate for spill prevention and response.

The Committee wrestled with many of the issues that lead to the various recommendations. But the most difficult is the issue of funding of recommendations and future work to enhance spill prevention, response, and recovery. Funding seems to be the common thread in many issues the Committee reviewed. Too many times the Committee debated points and worked to consensus only to find that funding is the basis of moving forward to resolve the issues. It would be irresponsible to say "Here is the issue and here is the solution; let's move forward," without discussing cost and funding concerns.

The Committee recommends that the Area Committee should work with its membership to identify projects that are needed to enhance oil spill prevention and response. For example, the area Environmental Sensitivity Index (ESI) mapping should be updated. The Area Committee, with proper funding and continued COTP leadership, should designate the updating criteria and upgrading cycle for ESI maps and fund the project accordingly. Another example is booming strategies. Historically, the DBRC, using industry funding, has researched the booming of sensitive areas, reviewed and revised booming locations, and updated booming strategies along the Delaware River and Bay. However, the recent closing of two local refineries – and the future of a third in question -- calls into doubt the availability of funding for these activities in the future.

In the years since September 11, 2001, funding for security issues relative to the Sector and in ports across the nation has increased immensely. Likewise, oil spill prevention, response, and recovery should be funded appropriately. The Committee recommends funding through the National Oil Spill Liability Trust Fund. This trust fund is a mechanism which already exists, which is dedicated, in part, to research and development, and which has been used for oil spill prevention, response, and recovery projects in other areas of the country.

The Committee has found many issues relative to oil spills that could be resolved with adequate funding and leadership. The regional port community as a whole has worked well together to

foster prevention, response, and recovery ideas and methodologies. The Committee also found an attitude of wanting to foster a proactive oil spill response environment among its members. The Committee feels this environment can be accomplished by enhancing the role of the Area Committee, working to encourage new active committee membership, and funding the committee for program development in the areas of submerged oil research, periodic updates of ESI maps for all coastal areas, establishing and maintaining national and port-specific oil spill web sites, developing a Geographic Information System (GIS) for oil spill response including protective and preventative booming schemes, and enhancing and the Physical Oceanography Real-Time System (PORTS®).

Levels of Communication/Communication Operating Procedure (R-4)

Recommendation: Provide for an enhanced communication to mariners relative to navigational hazards and reiterate to mariners their role and responsibility to report material and equipment lost overboard.

Questions were raised during discussions about the level and types of notification to mariners regarding navigational hazards. Discussion involved the various means and the federal agencies mariners would look to for navigational information. The obvious two agencies are the U.S. Coast Guard and the U.S. Army Corps of Engineers (USACE), with the communication of navigational hazards being the responsibility of the USCG. Today, more and more methods of communication are available to facilitate the exchange of information between individuals and organizations. These methods should be explored and communication procedures updated accordingly.

Currently, the U.S. Army Corps of Engineers, Philadelphia District, maintains and updates a website which provides the latest surveys of navigation channels. This is a public access website (http://www.nap.usace.army.mil/channel/index.htm) that allows anyone to view and download the latest channel exams. The District should evaluate the practicality of adding a channel survey schedule to the website to further inform the public of upcoming or proposed surveys. The website should be more user friendly for public use; for example, channel surveys should be named for ease of access.

With regard to communication of navigation hazards to the public, as stated above, ER1130-2-520, NAVIGATION AND DREDGING OPERATIONS AND MAINTENANCE POLICIES, 29 Nov 96, Paragraph 5.c. specifically addresses the public notification responsibility and states "The Coast Guard has authority to disseminate and maintain navigation safety information pertaining to obstructions and is the lead agency responsible for this type of information." The USCG will issue Marine Safety Information Bulletins (MSIB) when a hazardous navigation situation exists, and they will rescind/update that MSIB when conditions have changed. USACE will support the USCG, whenever possible within the constraints of authority and vessel availability, with supporting data to determine the nature and extent of the navigation hazard.

The USCG is the correct federal agency to communicate Marine Safety Information. Having a single federal agency responsible for communicating navigation hazards and restrictions to the public prevents the distribution of incorrect or differing information. The maritime community should be aware that the USCG is the single source for the status of navigation safety and restrictions. The USACE Philadelphia District information is viewed as providing a supplemental source of channel condition data via its website and the latest channel exams.

Another part of this issue concerns the amount of knowledge mariners have regarding their responsibilities to notify the USCG of materials or equipment lost overboard. It would seem, as a result of the *Athos I* incident, where submerged debris was a prime contributor to a major spill, that mariners may not know or understand their responsibility or the consequences of not

reporting materials or equipment lost overboard. It would seem prudent that the Mariners' Advisory Committee consider an outreach program to reiterate to mariners their responsibility to report, the consequences for not reporting, and the potential navigational impacts of unreported debris.

Debris Removal Program (R-5)

Recommendation: All efforts should be made to enhance detection of submerged objects and to strengthen lines of communication to mariners regarding hazards to navigation.

There was much discussion regarding submerged objects, floating debris, and communication of navigational hazards to mariners, especially since the 2004 *Athos I* incident was reported to have been caused by a submerged object in the vicinity of the ship's docking area.

Submerged objects in the channel or in the vicinity of the channel are hazards or potential hazards to navigation conflicting with the potential safe passage of all vessels including crude oil tankers. Through discussion, the Committee recognized that there are three requirements for a successful submerged debris program:

- Those responsible must report lost or sunken objects such as vessel equipment or cargo lost overboard;
- Channels and anchorage areas must be surveyed for submerged objects that pose a hazard to navigation (which is the mission of the U.S. Army Corps of Engineers); and USACE should communicate the information with other maritime stakeholders;
- Commercial dock operations, including marine transfer facilities, must communicate berth conditions, including draft, to vessels.

ER1130-2-520, NAVIGATION AND DREDGING OPERATIONS AND MAINTENANCE POLICIES, 29 Nov 96, specifically addresses the procedures and authorities of the U.S. Coast Guard and the U.S. Army Corps of Engineers (USACE) with regard to submerged obstruction in the navigation channel. Appendix B of that document is a signed Memorandum of Agreement (MOA) between USCG and USACE that defines how hazards to navigation are determined and the action that should take place to deal with them. Paragraph 5 of the MOA explains the required actions, including assessment of the impact to navigation.

The USACE Philadelphia District generally surveys all active navigation channels at least twice annually. Some areas that experience higher than average shoaling rates are surveyed more frequently. Additionally, the District will survey areas upon request of the USCG or port users if there is a suspected issue with regard to navigation safety.

Following the *Athos I* spill, the USACE Philadelphia District did perform a target obstruction survey of the Delaware River which identified hundreds of "hits" on the river bottom; however, none of these was within channel limits. Obstructions outside of the federal navigation channel limits pose a limited threat to safe navigation. To address submerged debris hazards outside the federal navigation channel limits (such as in private berthing areas), the DRBOSAC recommends that Congress fund a competitive grant program for submerged debris identification, prioritization, and removal. Such a program would enhance port community efforts to ensure safe berthing areas.

Although there are numerous submerged objects throughout the Delaware River, the USACE and the USCG currently have no authority or responsibility to remove or report them unless the objects are impacting the federal navigation channels or anchorages or creating a pollution threat. As demonstrated during the *Athos I* spill, however, objects adjacent to or below the plane of the federal navigation channel and anchorages could pose an increased risk during certain navigational or operational conditions. The Mariners' Advisory Committee or the Local Area Committee should be tasked with investigating whether an expanded submerged debris removal mission and capabilities would reduce the risk of spills caused by ships striking submerged debris. The MOA should be reviewed to ensure there is proper procedure for the reporting of potential navigational hazards and that such hazards are documented and charted, that action is taken, and that reports to mariners are accomplished in an efficient and timely manner.

Another issue that should be addressed is the importance of commercial dock operators, including marine transfer facilities, establishing safe berth guidelines and communicating those guidelines to vessels that call on them. In addition, operators should be required to periodically survey their berths as appropriate and communicate findings to vessels in a timely manner to ensure that ships come up the river at the appropriate draft.

Update NOAA Environmental Sensitivity Index Maps (R-6)

Recommendation: Update the 1996 edition of the Delaware Bay Environmental Sensitivity Index (ESI) maps and provide funding for this update and periodic updates of all coastal regions in the future.

The current edition of the Delaware Bay ESI Maps was produced in 1996. It is out of date and new environmental data and information should be incorporated. Data supporting the 1996 edition predated advanced Geographic Information System (GIS) capabilities now utilized by the natural resource agencies at the state and federal level, by non-governmental organizations, and academia.

The ESI maps are used by responders during the time of an oil spill incident to identify and assign protection and mitigation priorities. Watershed-based local industries likewise utilize Environmental Sensitivity Index (ESI) maps to identify required resource protection priorities and strategies during planning, drills, and real incident response. ESI maps are used as the basis for identifying sensitive areas for inclusion in the Area Contingency Plan (ACP) and as a further basis for completing the Sensitive Area Sheets contained within the ACP.

Since their creation, ESI maps have evolved and the version produced for the Delaware Bay no longer reflects the state of the art. Additionally, the current version does not contain up-to-date capabilities such as digital geo-referenced aerial photography produced by NOAA.

In view of the outdated nature of the existing edition of the ESI maps, it is imperative to update the maps to the current level of environmental natural resource data and information in order to adequately protect the natural resources of the Delaware River and Bay and the Atlantic Ocean Area of Responsibility for the USCG Sector Delaware Bay. With the development of a GIS Spill Management Database, the ESI mapping database should become an integral component of the ACP.

There should also be a national requirement that all ESI maps be updated on a regular and ongoing basis. The DRBOSAC recommends that updates be produced not more than every ten years, to ensure the accuracy of the maps and their ability to provide maximum response assistance and value. Congress should provide funding to NOAA to carry out the updating and to fund states and other federal agency participation.

Development and Maintenance of Area Protection and Countermeasure Plans (R-7)

Recommendation: The Sector Delaware Bay Area Committee should assume control of the existing protective booming plans and develop additional countermeasure plans for the entire Sector area. With the development of a Geographic Information System Spill Management Database, Protection Strategies and Countermeasure Plans should become an integral component of the Area Contingency Plan. Dedicated funding for the development of plans, testing of plans, and maintenance of plans must be provided. This same type of planning and testing should be provided nationally for all area plans.

Starting in the mid-1970s, the Delaware Bay and River Cooperative (DBRC) began developing protective booming plans for openings to wetlands along the Delaware River in the Philadelphia area where DBRC member refineries are located. This effort continued through 1990 when 16 plans had been developed and equipment to implement the plans had been procured and stored at member facilities. During this time frame the protective booming plans were tested and refined and used during spill responses. In 1992, DBRC contracted to have booming plans developed for all openings into wetlands of the Delaware River and Bay from the Betsy Ross Bridge in northern Philadelphia to the mouth of the bay. In 1993, DBRC contracted the preparation of an appendix to DBRC's response plan that contained all known environmental data (Environmental Sensitivity Index Maps, member company-specific information, and any other available information) and the protective booming plans into a single document which all member companies could reference to satisfy the OPA 90 regulatory requirements. Copies were provided to the states of Delaware, New Jersey, and Pennsylvania, the USCG Marine Safety Office Philadelphia, and the Environmental Protection Agency. The annex was four inches thick, printed in color, and weighed ten pounds. It could not be incorporated into the Area Contingency Plan (ACP) because of the cost to reproduce -- $350 per copy!

In 2000, DBRC contracted the conversion of the paper annex to electronic format in PDF documents, and copies were given to all who had the paper copies and to nonmembers of DBRC who requested them. Between 2000 and 2006, DBRC worked with New Jersey and Pennsylvania to develop plans for Delaware River openings into wetlands from the Betsy Ross Bridge to Trenton, NJ, which is the upper end of navigable waters. DBRC also worked with New Jersey to transform paper plans for ocean inlets into electronic format. In 2006, when the ACP was converted to electronic format, the protective booming plans were included.

DBRC continues to maintain the master plans and reviews the plans after every deployment. Major changes to the plans also were made based on lessons learned after the *Athos I* spill. The booming plans are now in a Geographic Information System (GIS) database, which DBRC has provided to the Coast Guard, the states, and member companies.

While DBRC has historically developed, maintained, and exercised the protective booming plans, it is a voluntary activity. The recent closing of two refineries in the Delaware Valley indicates that the industry may be going through significant changes, and DBRC may not be able

to fund such efforts in the future. The Area Committee should assume control of protective booming plans using the DBRC-provided GIS software. If a GIS system is developed for the Sector (recommendation R-10), the booming plans should become part of that system and should be supported and maintained by contracted resources.

The protective booming plans for openings to wetlands along the Delaware River and Bay are an important component of the oil spill response plan, but there is also a need for other countermeasure plans for resources at risk in the river, bay and ocean. The Area Committee should address this need. The Ecological Risk Assessment of lower Delaware Bay performed in 2006 as part of a consensus workshop sponsored by the Sector Delaware Bay Area Committee was the type of systematic approach that needs to be used throughout the area. The report of this workshop can be found at www.ecosystem-management.net/c/7/project-reports/. Such work will require a long-term effort.

Funding from the Oil Spill Liability Trust Fund should be dedicated to accomplish these long-term efforts to develop countermeasures as well as to maintain and exercise all protective plans.

New Recovery and Treatment Technology (R-8)

Recommendation: Funding should be allocated for additional research into new treatment technologies such as chemical agents for dispersants, surface washing, bioremediation, surface collecting, and miscellaneous oil spill control agents in fresh water as final clean up techniques for future oil spills within the Delaware River. The Area Committee should develop a section for chemical agents in the Area Contingency Plan.

During oil spill cleanup, mechanical techniques are used to remove most of the oil at a shoreline. However, such techniques leave behind small quantities of residual oil. This remaining oil still may be biologically available and may continue to cause damage to the environment, so it needs to be removed, and bioremediation may be the appropriate tool.

The use of various chemical agents can be an effective cleanup option. However, the chemical agents currently on the National Contingency Plan (NCP) Product Schedule (40CFR § 300.900 Subpart J—Use of Dispersants and Other Chemicals) have not undergone testing that provides sufficient information on their efficacy in fresh water and varying temperatures.

Under 40 CFR § 300.910 (a) (Authorization of use*) "…the Area Committees shall address, as part of their planning activities, the desirability of using appropriate dispersants, surface washing agents, surface collecting agents, bioremediation agents, or miscellaneous oil spill control agents listed on the NCP Product Schedule. ACPs shall, as appropriate, include applicable preauthorization plans and address the specific contexts in which such products should and should not be used. In meeting the provisions of this paragraph, preauthorization plans may address factors such as the potential sources and types of oil that might be spilled, the existence and location of environmentally sensitive resources that might be impacted by spilled oil, available product and storage locations, available equipment and adequately trained operators, and the available means to monitor product application and effectiveness."*

Based on these requirements, the Area Committee should:

- Research and catalogue the types of petroleum products that transit through the Delaware Bay and River, and
- Develop additional testing protocol for the Swirling Flask effectiveness test methods (described in appendix C to CFR § 300) to require using the types of oil that might be spilled in the Area, fresh water, and varying water temperatures.

After completion of the cataloging, the following tasks should be completed:

- Notification of the chemical manufactures on the NCP Product Schedule about the preauthorization plans and additional testing protocol for the Swirling Flask effectiveness test methods,
- Evaluation of the various petroleum products to determine which products are amenable to bioremediation,

- Determination of the different types of shorelines present throughout Delaware Bay and River and evaluation of which shoreline types would be amenable to bioremediation,
- Evaluation of the shorelines amenable to bioremediation and determination of what nutrients or biological conditions are needed to increase the natural attenuation rate of the petroleum products through bioremediation,
- Establishment of protocol for testing various chemicals during a spill of opportunity.

Without this research it is unknown which biologically-available petroleum products could be further removed after the completion of traditional mechanical removal techniques, thereby further reducing the overall impact to the environment.

Modernize and Update the Natural Resource Damage Assessment Type A Model Used for Small Spills (R-9)

Recommendations: Congress should reauthorize and provide funding to the Department of the Interior and NOAA for updating the Natural Resource Damage Assessment Type A computer models to reflect advances in computer modeling, in the effects of contaminants on the eventual return of natural and social resources to their pre-spill baseline conditions, and in current restoration procedures. Congress also should increase the damage cap from $100,000 to $1 million to realistically reflect today's restoration costs for small, but high value, habitats.

The Natural Resource Damage Assessment (NRDA) is the process by which Trustees of the resource management agencies document injuries and losses and determine damages when oil or hazardous material spills harm natural resources. Certain categories of parties responsible for a release or discharge, known as "responsible parties" (RPs), are liable for natural resource damages if the release or discharge results in injury to natural resources. Natural resources include land, fish, wildlife, plants, air, and water which the Trustees manage on behalf of the public.

Trustees must use the recovered damages to fund restoration, rehabilitation, or replacement of injured natural resources, or acquisition of equivalent natural resources. These actions, often referred to collectively as "restoration," are principally designed to return injured resources to baseline (i.e., the primary condition that would have existed if the release or discharge had not occurred). Compensatory restoration also can compensate for the public's interim loss of injured resources or services during the time period from the onset of injury until baseline is restored.

The NRDA Type A computer model procedure was designed for minor spills in coastal or marine areas and incorporates the Natural Resource Damage Assessment Model for Coastal and Marine Environments (NRDAM/CME). Users supply limited data, such as basic physical environmental conditions and the amount, location, and duration of the spill; then the NRDAM/CME model computes the physical fate of the spilled substance and estimates acute lethal effects (injury). The model then estimates and sums the cost (damage) of restoring to baseline pre-spill conditions and the value of certain lost interim public uses and services, such as hunting, fishing, bird watching, and beach visitation.

The existing Type A NRDA/CME model was last updated very early in 2000 and runs on the Windows 95 operating platform which is now completely out of date and not available to run this Type A model. The only alternative is the Type B model which entails assessing and calculating injury and damages in a labor-intensive and time-consuming process. This generally requires hiring specialized contractors and using massive amounts of resource agencies' staff time in compiling the required restoration plan and in its implementation. For small spills, this process is an unnecessary burden on both Trustee agencies and Responsible Parties.

Also, because Type A procedures are intended for minor spills, the regulations currently place a $100,000 cap on their use if Trustees intend to obtain a rebuttable presumption. In addition to the outdated operating platform, this $100,000 cap on restoration costs also is outdated. Under today's standards, that amount would not restore even one acre of high value wetlands. The cap should be increased to at least $1 million while still maintaining the rebuttable presumption option.

The practical value of this Type A program is that it is aimed at small spills and provides a low cost, fair, and scientifically defensible evaluation of resource injury, damages, and restoration costs, thus saving both the responsible party and Trustees time and money in coming to agreement on final restoration specifics. However, because of the loss of Type A computing capabilities, the result across the nation generally has been that small spills go unresolved, to the detriment of the public interest and the impacted environment and ecology. An updated program would enable an efficient resolution to small spills and finality to the Trustees' responsibility in those small spills.

Geographic Information System Spill Management Database (R-10)

Recommendations: Procure a spill management database using the Environmental Response Management Application jointly developed by NOAA and the University of New Hampshire as the framework. This system would be suitable for oil spill activities and Maritime Security activities. Activities include planning, exercises, and response to real events both natural and human induced. Funding for the initial development and for ongoing maintenance must be provided. A continuing source of funding could be the Oil Spill Liability Trust Fund.

Increasingly, more spill related data and tools are digital in nature. Tying data to a geographical map-based format is becoming commonplace and the three states in Sector Delaware Bay employ the same software platform. Recently the Sector has begun to transition to Geographic Information System (GIS) capability as well. What is lacking at this point is a centralized GIS spill management database platform. This GIS platform is needed to bring all spill related data into one centralized location, allowing responders access to the latest real-time data in a quick, user-friendly manner. A web-based portal offers many advantages as a tool to bring real-time data to responders. Real-time weather, tides, and current databases, to name a few, are available 24/7. Maps of natural resources also are maintained to varying degrees on the web. Many of these portals can be viewed in a Google Earth format making it easy to visualize in a typical GIS layering manner. One example is the National Wetlands Inventory maps of the whole United States which are available to the public with free access on the U.S. Fish and Wildlife Service website at www.fws.gov/wetlands/. Many spill management teams also have their own proprietary version of GIS-based spill management systems.

NOAA is ready to release a PDA version of the electronic Shoreline Cleanup Assessment Team (eSCAT) documentation that is digital except for the sketch function, which is still in paper/hard copy format. SCAT data captured digitally in the field can be transmitted into a digital access database at the command post for use by planning, operations, and natural resource damage assessment units. This digital data can be exported into a functional spill response GIS platform to establish and analyze situational awareness and spill progress and to target trouble areas in need of additional support.

The states within Sector Delaware Bay have GIS databases of their natural resources. Many of the federal agencies also have similar digital databases. The Delaware Bay and River Cooperative (DBRC) likewise has its version of a digital database that forms the core of a portion of the Sector Area Contingency Plan and the DBRC's own response management program. A centralized GIS database that can pull various existing disparate data into a real-time access portal to supply spill related decision making information is critical for a successful spill response.

There are a number of approaches to addressing this centralized GIS spill database platform issue. One approach is to use the Environmental Response Management Application (ERMA)

jointly developed by NOAA and the UNH. ERMA is a data platform capable of interfacing diverse spatial data sets into an internet-based mapping format in order to enhance decision making for hazard responses (such as oil spills) and restoration. ERMA is a web-based GIS application that combines real-time web databases and uses Google Earth as the basis of its GIS platform. This system has been successfully implemented and used in Southern New England and Puerto Rico[2]. Using this framework would save considerable development and implementation costs.

[2] Since this recommendation was originally written, ERMA was also successfully used in the Gulf of Mexico for the DEEPWATER HORIZON incident response.

Facility and Vessel Oil Spill Response Plans (R-11)

Recommendation: In consultation with the Area Committee, USCG Sector Delaware Bay should review the guidelines used for review of Facilities Response Plans required by 33 CFR Part 154. Sector Delaware Bay Area Committee should prioritize the sensitive areas in the Area Contingency Plan and provide guidance to the plan review staff as to the capabilities and timeliness of response required for sensitive areas. USCG Headquarters should strengthen the language of 33 CFR 155.1030 (h) so that Tank Vessel Response Plans address the requirements of the Area Contingency Plan for protecting fish and wildlife and sensitive environments. The local Captain of the Port should review the tank vessel geographic appendices for compliance with the local Area Contingency Plan.

33 CFR Parts 154 and 155 require facilities and certain vessels to prepare Oil Spill Response Plans. The regulations have very detailed requirements on how the plans are to be prepared and what they must contain. 154.1035 (b) (4) requires facilities to plan for protecting fish and wildlife and sensitive environments identified in the Area Contingency Plan (ACP). For tank vessels, 155.1030 (h) requires that information contained in the response plan be consistent with the most recent ACP. However, it does not require planning for wildlife and sensitive environments. 155.1045(i) requires geographic-specific appendices for each Captain of the Port zone but only requires listing of Oil Spill Response Organizations (OSROs) that are under contract for the Area.

As part of the investigation of these requirements, the Sector Delaware Bay Facility Plan Review staff was asked to explain the process used during review of facility plans in the Sector. The Sector was utilizing guidelines put out in the 1993 time frame before the Area Contingency Plans were developed. The plans for the facilities were not being reviewed to see if the requirements of 154.1035 (b) (4) were being met. The plans for vessels are reviewed at USCG Headquarters and the Sector has no role in that review. In fact, the local ACPs are not used in that review. The required geographic appendices merely list the response organizations under contract and do not take into consideration the local requirements for protecting sensitive areas and the contractors' ability to protect the areas as required by the ACP.

It appears that Sector Delaware Bay has now revised its guidelines for review of facility plans. Subsequent to the Sector presentation, at least one facility within the Sector was required during an inspection to have the information showing how the requirements of 154.1035 (b) (4) were being met. The Sector Delaware Bay Area Committee should review the guidelines used by the Facility Plan Review staff and provide guidance to plan reviewers as to what should be required in the specific areas above and below a facility's location on the river or bay and what should be reflected in the facility's response plan.

The Area Committee should establish a procedure for the evaluation of the Environmentally Sensitive Areas identified in the ACP for Sector Delaware Bay and develop a ranking system to protect fish and wildlife and sensitive environments. The ranking system should take into

consideration seasonal variations and weather conditions. The ranking should establish maximum response times for the deployment of the required booming strategies and commencement of recovery and mitigation activities. In accordance with 33CFR154 Subpart F Section 154.1045, *"The resources and response methods identified in a facility response plan must be consistent with the required resources and response methods to be used in fish and wildlife and sensitive environments, contained in the appropriate ACP. Facility owners or operators shall ensure that their response plans are in accordance with the ACP in effect 6 months prior to initial plan submission or the annual plan review required under §154.1065(a). Facility owners or operators are not required to, but may at their option, conform to an ACP which is less than 6 months old at the time of plan submission."* The Area Committee should update the ACP upon the completion of the ranking system and required response times and should provide guidance to the USCG facility plan reviewers. Facility Response Plan holders should be notified of the ACP revisions and Sector Delaware Bay should revise its guidelines for review of facility plans to ensure that the necessary revisions have been incorporated.

The majority of the large spills in the Sector Area involve tank vessels as shown in the Sector Delaware Bay Significant Spill Events document in the appendix of this report. The Sector and the Area Committee have no control over tank vessels and their capabilities to meet the requirements of the Sector Delaware Bay Area Contingency Plan. The Coast Guard needs to strengthen the language in 33CFR Part 155 to require that the geographic appendices for each Captain of the Port zone transited show how the vessel response plans will satisfy the ACP for the zone. The geographic appendix for a vessel plan should be forwarded to the Captain of the Port for the geographic area for review.

Submerged Oil (R-12)

Recommendation: Fund USCG research and development efforts for detecting, tracking, and recovering submerged oil. Use the Oil Spill Liability Trust Fund to fund the research and development effort as was done in the past for other oil spill research and development. When the detecting, tracking, and recovery technology is developed, the Area Committee should determine the quantities of detecting and recovery equipment required in a Sector depending on the volumes and types of heavy oil transported in the Sector.

Submerged oil is oil that sinks below the water surface. It may float submerged in the water column anywhere from just below the surface to just above the bottom. Submerged oil also may sit upon the bottom or even become imbedded in bottom sediments. The Delaware River and Bay has a history of submerged oil spills going back at least to the *Presidente Rivera* spill in July 1989 in which the spilled #6 bunker oil lost its buoyancy shortly after being discharged in the Delaware River near Claymont, DE. It was theorized that the normally just-barely-buoyant oil picked up sediment to the point that it sank in the brackish water. As the submerged oil moved down river into the bay and entered denser saltwater, some of the oil started to regain its buoyancy and resurfaced. Likewise some of the denser oil continued submerged down the bay and out into the ocean, and some of it was later found resurfaced as far away as the Carolinas, where chemical tests identified it as *Presidente Rivera* oil.

Once oil becomes submerged it can no longer be contained and recovered by conventional methods. Likewise, booming is no longer effective to protect industrial and public drinking water intakes and other sensitive areas. This became an issue at the Salem, NJ, nuclear power plant cooling water intakes during the *Athos I* spill, resulting in a shutdown of the nuclear power plant.

There are two submerged oil issues that must be addressed. First is the detection and tracking of the submerged oil in the water column (speed, direction and depth) or its location on or just above the bottom. Detection techniques must be able to differentiate oil on or near the bottom from the bottom sediments themselves and any benthic community inhabitants, such as sea grasses, algae, coral or other colonial assemblages. Second is the challenge of recovering the submerged oil. Methods must be developed that will recover the oil with minimal adverse impact upon the benthic community. Even in clear water, as was the case in the 1994 *Morris J. Berman* spill in Puerto Rico, recovery of submerged oil is costly and an environmental challenge.

There are a number of research studies directed at the submerged and heavy oil problem. Existing off-the-shelf as well as emerging technologies are being evaluated. The intent of USCG R&D is to develop detection and recovery technologies so that industry then can be required to provide these response capabilities where heavy oils are transported or stored.

Protective (Pre-booming) (R-13)

Recommendation: Booming docked vessels that are engaged in product transfer or loading/off loading activities should be a basic requirement in order to enhance spill response and containment of spilled material.

Booming as a protective strategy has been a constant in spill preparedness and spill response. Booming is a basic industry strategy to minimize and contain spilled material. Booming, the placement of protective or containment barriers in strategic areas, is one of the first response measures taken to help prevent the spread of a spill and to collect as much material as possible. Booming strategies are often outlined and discussed in Area Contingency Plans, Facility Response Plans, and Spill Prevention and Countermeasures Plans. In Sector Delaware Bay, response after a spill relies heavily on the booming strategies that have been developed. But protective (pre-booming), in the form of deploying boom around a vessel that is transferring, loading, or offloading its cargo, could further enhance the ability to contain and minimize the spread of materials should a spill occur. At present, only the state of New Jersey transfer of hazardous liquids regulations (58:10-23.11f2) requires protective booming or containment of docked vessels with cargoes. The regulation basically requires that *"no owner or operator of a refinery, storage, transfer terminal, or pipeline facility, or a vessel while in the waters of the State, shall transfer, or authorize or allow to be transferred any hazardous liquid between any such facility and a vessel, or among two or more vessels, unless, as prescribed by the department, either a boom or other containment device is in place as hereinafter provided, or the containment device is available, along with trained personnel, at the site of transfer operations on a standby basis for immediate deployment in the event of a discharge, spill or release during the transfer."*

Protective (pre-booming) of all docked vessels engaged in the transfer/loading or offload of product should be a consistent requirement among Delaware, Pennsylvania, and New Jersey. This requirement should cover oil cargoes including crude oil and materials with a flash point below 100. Specifications for booming requirements can be developed by the individual states but every attempt should be made for consistency to avoid misunderstanding of the requirements and to achieve consistent application of booming protocols throughout the estuary.

The State of Washington, for example, requires pre-booming of vessels transferring over water. There are two classes of transfer based on rates of transfer and the type of facility. Requirements include:

- Pre-booming a transfer, which means completely surrounding the vessel(s) and/or facility dock area directly involved in the oil transfer operation, or
- The use of alternate measures, which could include access to boom long enough to surround the vessel(s) and dock area involved in the transfer.

Although pre-booming of a docked vessel was not an issue in the *Athos I* spill or response, assuming the *Athos I* had successfully docked and was pre-boomed, the containment of product would have occurred; therefore, dramatically reducing the impact of the spill.

Physical Oceanography Real-Time System Enhancement (R-14)
Recommendation: Fund the upgrade, continued operation, and maintenance of the Physical Oceanography Real-Time System.

The Physical Oceanography Real-Time System (PORTS®) is a decision support tool that improves the safety and efficiency of maritime commerce and coastal resource management through the integration of real-time environmental observations, forecasts, and other geospatial information. PORTS® measures and disseminates observations and predictions of water levels, currents, salinity, and meteorological parameters, such as winds, atmospheric pressure, and air and water temperatures, which mariners need to know in order to navigate safely. The objectives of the PORTS® program are to promote navigation safety, improve the efficiency of U.S. ports and harbors, and ensure the protection of coastal marine resources.

The real-time tide and current data provided through PORTS® represent one component of NOAA's National Ocean Service (NOS) integrated program to promote safe navigation. PORTS® data, when combined with up-to-date nautical charts and precise positioning information, can provide the mariner with a clearer picture of the potential dangers that may threaten navigation safety. NOS fulfills its navigation safety mission in close concert with other federal agencies, such as the U.S. Coast Guard and the U.S. Army Corps of Engineers.

The prevention of maritime accidents is the most cost-effective measure that can be taken to protect fragile coastal ecosystems. In 2004 alone, NOS's Office of Response and Restoration responded to more than 120 events, including the release of 270,000 gallons of crude oil into the Delaware River near Philadelphia, and the spill of more than 400,000 gallons of bunker oil in Alaska. One major oil spill such as the 1989 *Exxon Valdez* accident can cost billions of dollars and destroy sensitive marine habitats critical to coastal ecosystems. PORTS® provides information to make navigation safer, thus reducing the likelihood of a maritime accident. The system also provides information to mitigate damages from a spill, should one occur. Additionally, PORTS® provides real-time data input to trajectory modeling, helping to enhance the predictive capabilities that can improve response decision making and outcomes.

PORTS® has the potential to prevent shipping accidents and subsequent environmental damage and save millions of dollars in response, restoration, and damage claims. PORTS® is accessible to maritime users in a variety of user-friendly formats, including telephone voice response and the internet. PORTS® also provides forecasts via numerical circulation models. Telephone voice access to accurate real-time water level information allows United States port authorities and maritime shippers to make sound decisions regarding loading of tonnage based on available bottom clearance, maximizing loads, and limiting passage times without compromising safety.

Continuous funding of the operation and maintenance of PORTS® is not part of NOAA's budget and relies on funding from various state and local agencies. These funding sources are not guaranteed. In uncertain economic times like the present, they may be reduced or eliminated. Therefore, Congress should authorize and fully fund federal maintenance of the PORTS® system.

Also, the PORTS® system should be upgraded to include new and emerging technologies. One specific example is the CODAR system for ocean current and wave monitoring. A transmitter sends out a radio frequency that scatters off the ocean surface and back to a receiver antenna. Using this information and the principles of the Doppler shift, this system is able to calculate the speed and direction of the surface current. This capability, when applied to spill response, would greatly enhance the effectiveness and efficiency of strategies for controlling surface oil and recovering it.

Use of Volunteers during Oil Spill Emergencies (R-15)

Recommendation: Modify the Sector Delaware Bay Area Contingency Plan to coordinate with and benefit from Affiliated Volunteers and Convergent Volunteers cooperating with the Unified Command during an oil spill response.

At the national, state, and local level there has been much discussion on the use and management of volunteers during a major oil spill incident. There are two distinct volunteer types:

- Affiliated Volunteers (AVs), who are those associated with a government agency (federal, state, local and/or tribal) or non-governmental organization (NGO) and who have been trained for a specific role. (i.e., Tri-State Bird Rescue and Research Organization, Oil Wildlife Care Network [OWCN], and the Coast Guard Auxiliary); and
- Convergent Volunteers (CVs), who are those with no connection to a government agency or NGO (e.g., those who walk in to the Incident Command Post to volunteer and those with no response training, background, or previous experience who undertake activities on their own).

While the Area Contingency Plan (ACP) Sections 4300, 4310, 4320, 4330, 4340 and 4350 have established the framework for volunteers and volunteer coordination, the Committee believes that the issue of convergent volunteers should be clarified to enhance their use, to ensure the safety of these volunteers, and to provide Unified Command with a set of guidelines for using volunteers.

To date, the issue of a massive influx of volunteers at a spill has not been a major problem in Sector Delaware Bay. Though volunteers do make themselves available, it has not been an issue that has adversely impacted a response. This is due mainly to the small number of volunteers, the areas impacted, and the agencies and organizations that have been associated with volunteers.

Among the issues to be resolved (and beyond the scope of the DARBOSAC) are coordination of the practices of the individual states—Delaware, New Jersey, and Pennsylvania—regarding their general requirements for volunteer use, training requirements (such as Community Emergency Response Team (CERT) training), and potential liability issues. While working with the Area Committee, each state should decide the best approach for its particular situation.

The Committee recommends that Affiliated Volunteer Groups establish a task list and associated training for convergent volunteers. CVs should follow the guidelines for training and task assignment established by the Affiliated Volunteer Group to which they are assigned. In addition, CVs should not be assigned to tasks that could be considered hazardous and that would require extensive Hazardous Waste Operations and Emergency Response Standard (HAZWOPER) or other specialty-type training. AVs and CVs can perform a variety of important functions such as checking creeks and shallow areas for oil, observing boom and sorbents locations for issues, meeting with the public to explain why an area has been deemed off limits, and assisting with supplies and transportation.

As outlined in the publication "Training Marine Oil Spill Response Workers Under OSHA's Hazardous Waste Operations and Emergency Response Standard" (OSHA Booklet 3172, 2001), all personnel should be "trained to the highest level of responsibility you may assign them." This guidance should hold true for all personnel including volunteers.

The Sector Delaware Bay Area Committee should review the Volunteer Section of the ACP and consider including the following:

- Minimum training should be established for all AVs that would anticipate working on an oil spill under the direction of the UC in accordance with the National Response Framework, National Incident Management System (NIMS) and the Incident Command System (ICS). For AVs, this training should include, at a minimum, IS-100, "Introduction to Incident Command System", IS-700 "Introduction to NIMS", and ISC 800 "Introduction to National Response Framework". IS-100 would be the minimum training requirement for all CVs and individual AVs.

- Within the Incident Command structure a position should be established to coordinate volunteers, or an existing position within the planning or operations sections should be given duties as the Volunteer Group Coordinator (VGC). The role of the VGC should include establishing a volunteer organizational structure as needed, developing the integration of AVs into the structure and directing CVs to appropriate AV groups; and ensuring effective communication and interface between the AV group leaders, Incident Command, and the operations being conducted.

- A list of jobs/activities that AVs and CVs can perform should be developed and AVs should be assigned to develop a job safety analysis (JSA) for each. The JSA should include a description of the job/activity, a detailed list of tasks to be performed in a particular activity, potential hazards for each task outlined, identification of required personal protective equipment and protective measures, and establishment of training requirements.

The issues of utilizing volunteers and volunteer coordination should be addressed in every region and included in all ACPs in a way that best identifies and integrates specific local resources, opportunities, and differences that may exist. Volunteer issues should be resolved prior to a spill. These are not issues that are best handled during the agitated state of a response.

The following language is presented for consideration as an addition to the Position Checklist in the ACP or the USCG Incident Management Handbook (IMH):

> ***Volunteer Group Coordinator (VGC)***
> *The Volunteer Group Coordinator's function is to establish a volunteer organization structure and recommend measures for assuring appropriate Affiliate Volunteer Groups are engaged. The VGC will provide direction for developing the integration of AVs into the structure and directing convergent volunteers to appropriate AV groups. The VGC*

will ensure that effective communication and interface is established between the AV group leaders, Incident Command, and the operations being conducted.

The major responsibilities include:

a) Obtain a briefing from the Planning Section Chief,Ensure all Affiliate Volunteer (AV) groups are briefed on response needs and the Safety Plan,
b) Prepare an Organizational Assignment List (ICS-203) and Organization Chart (ICS-207) for the volunteer organizations,
c) Establish a meeting schedule with the AVs,
d) Maintain a list of the current status and location of all AV group resources,
e) Review each AV group's Safety Plan, including personal protective equipment needs and requirements,
f) Review task lists prepared by AV groups for their own members and CVs and approve the associated training, safety procedures, and required protective equipment for each task,
g) Assure that applicable state requirements for volunteer registration be maintained for state- or federal-organized and managed volunteers,
h) Determine the need for dedicated AV group volunteers,
i) Brief the Planning Chief on current status of the volunteer organization,
j) Provide advice on volunteer usage to the Planning Chief,
k) Participate, as required, in the tactical meeting and other meetings.

Pre-Cleaning Beaches and Shorelines (R-16)

Recommendation: In order to maximize spill response resources, increase efficiency of the clean up, and minimize disposal cost, the Sector Delaware Bay Area Contingency Plan should be modified to identify sites where pre-cleaning of beaches and/or shorelines prior to oil impact is an option. The Area Contingency Plan also should identify available resources that can perform the function and identify possible disposal options.

During an oil spill, such as the *Athos I*, there are typically thousands of tons of contaminated debris that has to be recovered, transported, and disposed. These tasks require that trained responders spend countless hours dressed in the appropriate Personal Protective Equipment (PPE) because the debris, such as wood, branches, trees, trash, etc., must be handled and disposed of as contaminated material. Typically, this operation is very expensive, time consuming, and wasteful since disposal sites are typically already overburdened . In addition, it removes from the shoreline the natural wrack which is important to the ecosystem.

In order to maximize responders' time and save the cost of PPE and disposal, "clean" debris that is expected, due to tide and wind projections, to be in the path of spilled oil should be identified, removed and disposed of before it can be contaminated by the oil. Due to their importance for the natural ecosystem, natural debris, such as logs, twigs, algae mats etc., should be relocated on site out of the path of expected oiling so as not to remove these elements from the environment. Garbage and other man-made waste should be disposed of properly. Disposal options will be greater since much of this uncontaminated debris can go to local landfills or other re-use needs within the area.

Debris removal can be accomplished by groups of volunteers or paid contractors who would not need specialized training under that Hazardous Waste Operations and Emergency Response Standard. Ideally, groups should be organized ahead of a spill.

Debris Removal Program (R-17)

Recommendation: Consideration Should Be Given to a Floating Debris Removal Mission for Sector Delaware Bay

Floating debris, though it may not cause an imminent danger to larger vessels, has the potential to place smaller vessels at risk. In addition, the accumulation of this debris has required extensive clean-up efforts after a spill has occurred. Large, significant, and potentially damaging debris is regularly observed in the Delaware River especially after storms and flood events. This debris has the potential to impact navigation and poses a pollution risk.

The EP 1165-2-1, DIGEST OF WATER RESOURCES POLICIES AND AUTHORITIES, 30 Jul 99, Paragraph 12-15 states "Action by the Corps in removing drift or debris from navigable waterways is generally limited to the removal and disposal from the authorized project limits and immediate adjacent waterway areas in the interest of general navigation." This reference further clarifies that harbor debris missions are specifically authorized by Congress only in designated harbors. Philadelphia and the Delaware River currently are not listed by Congress as an authorized debris mission harbor. The U.S. Army Corps of Engineers, Philadelphia District, currently does not have floating debris collection equipment in contrast to New York and Baltimore districts which have authorized debris collection missions and have equipment, staffing, and funding to support debris collection activities.

In order for Philadelphia District to perform a debris collection mission, capital investment in equipment and facilities, increased staffing, logistical planning, and possibly real estate acquisitions would be required. A general assumption, without performing an in depth study to quantify the amount of floating debris in the Delaware River, would estimate a capital investment cost to prepare for a debris mission as:

- One debris collection vessel (New York has three debris collection vessels; Baltimore and Norfolk each have one vessel) -- depending on vessel specifications, $10 million to $15 million.
- Land-based equipment to handle debris retrieved from the river, such as a crane, dump trucks, loaders, etc. -- $500,000 to $1million.
- Facilities for the mission, such as a debris offloading pier -- $3 million to $5 million.

Using these estimates and assumptions, the capital cost to stand up a floating debris collection mission could be in the range of $14 million to $21 million.

Additional cost to routinely carryout the mission would include an increase in staff to operate a debris collection vessel with a minimum crew of five -- operator, engineer, crane operator, and two deckhands -- and staff to manage the land-based disposal operation with possibly three or four field personnel and supervision.

The debris collection mission also would require an additional annual Operations and Maintenance funding allocation in order to support the labor, equipment and facility costs. The annual funding required to perform this mission likely would run several million dollars.

Identify, Obtain, and Catalogue Completed and Ongoing Scientific Research on the Delaware Estuary. Provide Public Access to these Data and Utilize these Data to Ensure the Protection of Environmentally Sensitive Areas throughout the Delaware Estuary. (R-18)

Recommendation: Provide dedicated funding to an appropriate agency or organization, such as the Congressionally-authorized Delaware Estuary Program, to catalogue and share existing data on oil-associated environmental effects, including effects of spills, and on the ecological status of the Delaware Estuary; to identify information gaps; and to work with all Delaware Estuary program partners to support oil spill-related scientific analysis and research to fill vital information needs. Develop a mechanism for ensuring that all present and future research is catalogued and made publicly available.

An inclusive and open process involving federal, state, and local agencies and academia should be used, and efforts should include:

- An inventory of all existing data associated with the Delaware Estuary, its health, habitats, impacts, and needs;
- A gap analysis to ensure a thorough understanding of all research needed to understand and address concerns about the Delaware Estuary and the individual and cumulative effects and impacts of oil spills;
- A strategy and dedicated funding for filling data gaps, including possible baseline monitoring for oils in the system;
- An open process by which all existing and new data are made available in a readily-accessible format; and
- Ensuring that this work is revisited on five-year cycles.

There are a variety of strategies for accomplishing these tasks, including white papers, symposia, work groups, and grants.

Identification and Prioritization of Restoration Needs and Mitigation Projects (R-19)

Recommendation: Provide dedicated funding to an appropriate agency or organization, such as the Congressionally-authorized Delaware Estuary Program to identify and prioritize restoration needs for mitigating the harm of oil spills large and small and to identify existing and/or emerging restoration projects that can be implemented.

In the event of a spill on the Delaware River there is always a need for mitigation, the use of beneficial environmental projects to restore health to the ecosystems that have been harmed There is a need to identify projects that are ready for implementation that would serve as suitable mitigation of the ecological harms resulting from pollution incidents and oil spills. These environmental projects can then be utilized to address the injured resources and ecological harm through processes such as the Natural Resources Damage Assessment (NRDA) program.

There are initiatives ongoing in the Delaware River community that are already identifying beneficial environmental activities and projects that could serve as effective mitigation opportunities for all areas and types of injury. However, these prioritization efforts and the projects identified are largely unfunded.

The Committee recommends that Congress:

- Provide dedicated funding through the Delaware Estuary Program to support the Regional Restoration Initiative to identify, catalogue, and prioritize needed restoration activities and projects in Sector Delaware Bay and to ensure that science-based tools are provided to NRDA and to restoration decision makers.

- Provide a competitive grants program through the Delaware Estuary Program to support initiatives and entities to fill project gaps by cultivating new project development as well as cataloguing restoration efforts currently underway or being planned in the region.

- Provide a competitive grants program that supports needed restoration activities and projects within the Delaware Estuary that do not meet the constraints of the NRDA program (spill restoration of direct damages by a responsible party).

Media/Public Relations (R-20)

Recommendation: The Coast Guard should increase public education about and access to information about oil spills before, during, and after spills by developing an official, comprehensive Delaware River and Bay oil spill information web site to which the public and all stakeholders have access. Information on the web site should be updated on an ongoing basis.

The Coast Guard should be more proactive, on an on-going, non-emergency basis, in providing the media and stakeholders (industry, other agencies, and interested public) with a wider range of information about oil spills and oil spill response. Aggressive dissemination of pre-spill educational material—in addition to incident news reporting—could increase the accuracy of information in the marketplace and foster understanding of spill-related issues. It also could help assure public acceptance of response activities and cooperation with response personnel during an incident.

One way to achieve such dissemination would be to institute an official, comprehensive oil spill web site that is extremely user friendly, easy to find and access, and easy to use. The site should use layman's language and be regularly maintained. A core site to be used nationwide could be built by the Public Information Assistance Team. That core would include basic information that is common to all Sectors such as: definitions, explanation of laws and duties, roles of different agencies, oil types and how they differ during a spill, links to various studies, etc. Each Sector then could build on that core by adding its Area Contingency Plan, area spill history and damage assessments, sensitive area maps and explanations of booming strategies, local volunteer involvement and ways to help or become trained to help, and a calendar for meetings, etc.

In short, the site should contain everything interested parties might need or want to know and everything a spill response team wants to tell them. It should make generous use of links, including links to Twitter, Facebook, and other social media. If well done, the site should become THE place everyone knows to go for official, accurate spill-related information, whether before, during, or after a spill.

During a spill, the site could be used to disseminate information to the public specific to the ongoing response. It could be used to pass information about the extent and other effects of the spill. For example, the location of protective booming sites and how boaters should react when approaching such sites could be posted.

Such a web site would be valuable in improving the flow of information, in fostering understanding, and in increasing the accuracy of information in the marketplace. Given the status of the media today, this web site would be a more dependable way of getting information out in a more complete and timely manner. It also could encourage aggressive information sharing by all stakeholders. However, this web site would not replace regular press meetings during times of emergency.

Delaware River and Bay Oil Spill Advisory Committee: Other Considerations

The Committee and subcommittees discussed a variety of topics throughout their deliberations. However, some topics did not result in formal recommendations because they may not have been completely researched or developed or because they were not considered to meet the standard for a recommendation. These topics included the following:

Spill of Opportunity Testing Policy

For Consideration: At the local or regional level, a policy should be in place to foster the advancement of scientific research concerning the consequences to the environment from response techniques and countermeasures. This policy should encourage the experimental use of various countermeasures and include guidance for such use in areas that are set aside to be used as control sites.

During an oil spill it is difficult to organize and plan research projects that can have meaningful and defendable results. However, a policy at the local area or regional level could help foster the implementation of such research. Currently, there is no formal guidance available to help direct research. As there are presently no research opportunities to test oil countermeasures in the environment, the only opportunities for such research are during an actual oil spill. Thus, being prepared with a prioritized list of the types of research that could be performed and the knowledge that this is important to the response community will allow the Environmental Unit to address such research during a spill. The opportunity to learn from spill responses could be a major positive outcome that leads to improved spill response and minimizes environmental damage in subsequent events.

Scientific research during an actual oil spill needs to be pre-planned in order to improve spill responses, increase efficiency, minimize damage, and enhance recovery of the environment.. The Area Committee or the Regional Response Team should prepare a policy with regards to scientific research opportunities during an actual oil spill response.

Job Aids for use by Responders Dealing with Oiled Wildlife, Plants and Fish

For Consideration: The Sector Delaware Bay Area Committee should establish a wildlife, plants of interest, and fish database such that, during any spill, information can be provided immediately that will enable responders to protect wildlife, endangered plants, and fish and to take appropriate action if these natural resources are oiled.

During oil spills there are various plans for initiating the notification of bird rescue organizations. However, procedures for aiding responders with the identification, reporting and handling of oiled birds and other common wildlife are not addressed in any detail. Wildlife are

sometimes reported as oiled when they are not in fact oiled but their natural coloring makes it appear to the uneducated observer that they are oiled. The probability of improperly handling already-distressed wildlife increases if the proper information is not provided to people working in the field who will be the first to encounter wildlife. Likewise, responders doing shoreline cleanup will be working in environments where protection of sensitive plants is possible if they have information that makes identification of plants of concern possible.

There are no formal job aids available to provide information to responders in a timely and succinct manner. Various resources are available for compiling the necessary information but no common site or document is available. It would benefit the response effort to have such information readily available in a format that would allow job aides to be generated quickly depending on the specifics of a given spill and location.

The Sector Delaware Bay Area Committee should collect data for all local wildlife, plants of interest, and fish in the area in a format that easily can be accessed and provided to responders in the field. This information even could be housed on the suggested oil spill web site (recommendation R-20). This material should include documentation, reporting, and preservation procedures as well as cautionary information regarding oiled and deceased wildlife, plant life, and aquatic species. General information could be developed on a national basis with important local/seasonal information provided on an Area basis. The establishment of a geographic information (GIS) spill management database (recommendation R-10) would greatly facilitate this effort.

Economic Recovery

Economic recovery also was discussed, but the subcommittees had difficulty coming to a final decision on the issue. The Committee sensed there should be a methodology to better assess and understand the economic impact of an oil spill. However, within the time frame available, the Committee was not able to work out the data elements that should be included or to figure how to collect the data and who would be responsible for developing the methodology.

Committee and Subcommittee Meetings – Overview

The initial meeting of the Delaware River and Bay Oil Spill Advisory Committee (DARBOSAC) was opened with administrative topics by LCDR Nakeisha Hills and opening remarks by CAPT David Scott who welcomed everyone and outlined the mission of the Committee.

An election of officers was held and the following presentations were made to the Committee:

Mrs. Georgia Abraham, who is responsible for organizing Federal Advisory Committees at the U.S. Department of Homeland Security, gave a general presentation on the Federal Advisory Committee Act and the responsibilities and functions of the Committee.

MST3 Weldon James presented Oil Spill 101 which covered oil movement, movement with the current, containment techniques, exclusion and diversion technique, types of skimmers (portable shallow water skimmers, oleophilic skimmers ,Weir skimmers and Vessel Operating Skimming Systems), types of absorbents (natural organics, natural inorganics, and synthetics), clean-up techniques, and the use of in-situ burns, biological agents, gelling agents, and dispersants.

Gerald Conrad, Director, Contingency Planning, U.S. Coast Guard Sector Delaware Bay, gave an overview of the *Athos I* incident, including state requirements for vessel booming, tank vessels arrival drafts (*Athos I* arrived into the channel with a depth of 36.5 feet draft), and the two week time frame to decide on a port of refuge.

Gerald Conrad from U.S. Coast Guard Sector Delaware Bay also gave a presentation on the *Athos I* after action report, which included highlights of multilingual safety briefs, safety incentive programs, and a renewed commitment to developing relationships through participation in area committees and oil spill exercises with local and federal agencies, utilizing local environmental experts to expedite the oil response efforts, state representation in the Unified Command, having predetermine lead agencies for response incorporated into Area Contingency Plans, ongoing effort of the Captain of the Port to identify facilities that will accept damaged vessels, and an intake early warning system that is now included in the Area Contingency Plan.

General Committee meetings early on were utilized as information and educational sessions. The information portion of the meeting was to update the Committee on process issues and the topic each subcommittee was discussing or researching. The educational portion of the sessions was to help inform Committee members on the status of oil spill preparation and response in the Delaware River and Bay and other topics needing a Committee overview.

As an example, the January 21, 2009, meeting featured a presentation entitled Oil Spill 102, which was an Overview of Oil Spill Prevention, Planning, and Response in Sector Delaware Bay by Eugene Johnson, then President, Delaware Bay and River Cooperative (DBRC). The presentation discussed the current status of Oil Spill Prevention, Planning and Response and the roles and responsibilities of DBRC and others.

In addition, Ed Doyle, vice chair of the Committee, provided an Overview of Prevention and Planning which discussed the Area Contingency Plan (ACP) and Facility and Vessel Response Plans. Other topics discussed during that meeting included: planning under the ACP; the Port Community; wetlands; examples of specific booming strategies at Big Timber-Oldmans Creek and Oldmans to Pea Patch Island, Darby Creek; collection booming; and sensitive areas such as Tinicum Island.

The Committee also entertained outside comments and presentation such as that requested by Alfred J. Kuffler of Montgomery McCracken Walker & Rhoads LLP on the topic of safe refuge and a presentation from Kurt Hansen, USCG R&D, on submerged oil.

A typical subcommittee meeting would involve specific areas of interest. The following are examples of how the subcommittee's worked:

Early on the **Prevention Subcommittee** used its meeting to discuss the following areas:

- Research and review previous incidents that resulted in oil spills in the Delaware River and Bay. What caused them, what lessons were learned, what regulations and/or recommendations followed the investigations, how were these enacted and have they worked?
- Investigate debris removal programs that are reportedly in effect in Baltimore and New York harbors. Large, significant and potentially damaging debris regularly is observed in the Delaware River, especially after storms and floods. This debris has the definite potential to impact navigation and poses a pollution risk. Determine whether to recommend that a similar program be funded locally.
- Determine the effective levels of communication down to the hands-on seafarers on vessels using the waterways. Are recommendations, suggestions, and requirements from sources such as the DARBOSAC effectively reaching the people using the river and bay? Conversely, is there an effective conduit for their comments and concerns to be heard by committees such as the DARBOSAC?
- Determine how commercial fisherman play into the overall use of the river and their potential to be a threat to tankers and other vessels that could result in an oil spill (offshore lightering example quoted).
- Investigate the relationship between speed of vessels transiting the river and the surge/suction effect they have on tankers moored alongside docks. Research recent incidents and offer suggestions as to how to mitigate.
- Research the difference in booming strategies in use in Pennsylvania and New Jersey. Determine effectiveness and suitability and make recommendations as to which way to go.
- Suggestion: Investigate USCG's review of Facility Response Plans and how they are integrated with the Area Contingency Plan. Determine if the plans can effectively deliver meaningful and effective responses in terms of both equipment and personnel.

The **Response Subcommittee** at one meeting conducted an overview of OPA ’90 regulations, reviewed how Sunoco provides emergency response to incidents which may occur at the refinery, and reviewed the use of volunteers during an oil spill. In addition, members listed topics for further discussion, such as:

- Spill of opportunity policy for testing response products
- Place of refuge
- Wildlife rehabilitation job aids
- Additional protection strategies and mapping
- Spring bird and horseshoe crab migration issues

The subcommittee also set assignments for collecting further information or starting to develop information for possible draft recommendations for the Committee on topics such as:

- Definition of Response
- Volunteers
- Pre-Cleaning Beaches/Shoreline
- Submerged Oil
- Media/Public Relations
- Safe Refuge
- Wildlife Rehabilitation
- Enhancement of the Physical Oceanography Real-Time System (PORTS®)

The **Mitigation/Recovery Subcommittee** worked to compile information on previous spills and "lessons learned"; members requested information on the "human dimension of spill response" and a presentation on the National Resources and Damage Assessment (NRDA) process.

In addition, members discussed economic concerns in terms of industry economics and business interruption, social and recreational economics, returning a riverbank to pre-incident conditions, opening the river to commerce, and the possible conflict between economic and environmental interests. They discussed what information may be lacking on endangered species and how information could be updated. They also discussed the role of environmental sensitivity maps (ESI), the fact that the maps are not current and discussed a possible recommendation regarding maintenance and sustainability of ESI and the funding and resources necessary to update maps.

The subcommittee’s mission statement was to identify mitigation and recovery recommendations that will minimize or eliminate extended environmental and economic harms that negatively impact the Delaware River and Bay environment, community, and business region in the aftermath of an oil spill.

Differences

As expected, all of the subcommittee discussions took time for participants to understand each topic or issue, to decide the relevance of each topic and to shape a recommendation to be brought before the full Committee. As also would be expected, throughout the various discussions some issues required a more substantial educational process before members could fully appreciate the

concerns, while other issues required more time for discussion and debate in an effort to reach consensus. For example, the use of volunteers during an oil spill and upgrading the Natural Resource Damage Assessment (NRDA) process were both robust discussions.

On the volunteer issue, ultimately two proposals were offered to the full Committee. The proposal that was not adopted recommended that all volunteer activities must strictly conform to the National Framework. Overall, the Committee found this too restrictive for the idea it wanted to promote and adopted the recommendation as written in R-15.

Proposing alternatives or modifications to the NRDA process to address small spills -- spills that individually might not meet established guidelines or thresholds but collectively might add up to a significant quantity -- proved equally challenging. Although the subcommittee came to agreement on a recommendation as written in R-9, the consensus required lengthy discussion.

Report Preparation

Each subcommittee prepared its own recommendations for inclusion in the Committee's final report. All recommendations then were brought to the full Committee where they were discussed thoroughly and each was individually subjected to a vote. This report was then compiled with help from many people and was made available to Committee members for review as a whole document. The report was unanimously approved by the Committee at its final meeting on December 16, 2010.

Appendix A – Delaware River and Bay Oil Spill Advisory Committee Charters

Original Charter (October 2007)

UNITED STATES DEPRTMENT OF HOMELAND SECUTITY
UNITED STATES COAST GUARD
DELAWARE RIVER AND BAY OIL SPILL ADVISORY COMMITTEE

Committee's Official Designation: (Title)
Delaware River and Bay Oil Spill Advisory Committee.

1. Authority:
As provided for in section 607 of the Coast Guard and Maritime Transportation Act of 2006, Public Law 109-241, this charter effects the establishment of the Delaware River and Bay Oil Spill Advisory Committee (DRBOSAC). This Committee is established in accordance with and shall operate under the provisions of the Federal Advisory Committee Act (FACA), 5 U.S.C. App.

2. Objectives and Scope of Activities:
The DRBOSAC shall provide advice, recommendations and a ranking of priorities for measures to improve the prevention of and response to future oil spills in the Delaware River and Delaware Bay. Not later than 18 months after the appointment of member the Committee, it shall provide a report to the Commandant of the Coast Guard, the Governors of the States of New Jersey, Pennsylvania, and Delaware, the Committee on Commerce, Science, and Transportation of the Senate and the Committee on Transportation and Infrastructure of the House of Representatives, detailing those recommendations and priorities.

3. Description of Duties:
The duties of the DRBOSAC are solely advisory in nature.

4. Officials to Whom the Committee Reports:
The DRBOSAC shall report to the Commandant of the Coast Guard through Commander, Sector Delaware Bay; Commander, Fifth Coast Guard District and Commander, Atlantic Area.

5. Agency Responsible for Providing Support:
The Coast Guard shall provide support to the DRBOSAC.

6. Estimated Annual Operating Costs and Staff Years:
The estimated operating cost of the DRBOSAC is $770,000, which includes 1.5 staff years of support and includes the rental costs of the facilities, travel, and accommodations for the Committee members based on per diem rates and contractor support to facilitate meetings and produce the final report.

7. Designated Federal Officer:
A full-time or permanent part-time employee of the Coast Guard shall be appointed the

DRBOSAC Designated Federal Officer (DFO). The DFO or his/her designee shall approve or call the DRBOSAC meetings, approve meeting agendas, attend all Committee and subcommittee meetings, adjourn any meeting when he/she determines adjournment to be in the public interest, and chair meetings when directed to do so by the Assistant Commandant of Response, Office of Incident Management Preparedness (CG-3RPP)

8. Estimated Number and Frequency of Meetings:

The DRBOSAC shall hold its first meeting not later than 60 days after the date on which the Commandant completes the appointment of members of the Committee. Thereafter, additional meetings will be held at the call of the Chairperson with the approval of the Designated Federal Officer. Committee meetings shall be open to the public unless a determination is made by the appropriate DHS official in accordance with DHS policy and directives that the meeting should be closed in accordance with subsection (c) of 552b of title 5, United States Code and announced in the Federal Register at least 30 days in advance.

9. Duration and Termination:

As authorized by section 607 of Public Law 109-241, the DRBOSAC shall terminate 18 months after the date on which the Commandant completes the appointment of the members of the Committee.

10. Chairperson and Vice-Chairperson:

At its first meeting, the Committee shall elect by majority vote one of the members of the Committee to serve as Chairperson and one of the members as Vice-Chairperson. The Vice-Chairperson shall act as Chairperson in the absence of or incapacity of the elected Chairperson or in the event of a vacancy in that office.

11. Member Composition:

The DRBOSAC shall consist of 27 voting members who are appointed by and serve at the pleasure of the Commandant of the Coast Guard and who have particular expertise, knowledge, and experience regarding the transportation, equipment, and techniques that are used to ship cargo and to navigate vessels in the Delaware River and Delaware Bay, as follows:

(A) Three members who are employed by port authorities that oversee operations on the Delaware River or have been selected to represent these port authorities, of whom
  (i) one member shall be an employee or representative of the Port of Wilmington;
  (ii) one member shall be an employee or representative of the South Jersey Port Corporation; and
  (iii) one member shall be an employee or representative of the Philadelphia Regional Port Authority.

(B) Two members who represent organizations that operate tugs or barges that utilize the port facilities on the Delaware River and Delaware Bay.

(C) Two members who represent shipping companies that transport cargo by vessel from ports on the Delaware River and Delaware Bay of whom at least one may not be a representative of a shipping company that transports oil or petroleum products.

(D) Two members who represent operators of oil refineries to the Delaware River and Delaware Bay.

(E) Two members who represent state-licensed pilots who work on the Delaware River and Delaware Bay.
(F) One member who represents labor organizations whose members load and unload cargo at ports on the Delaware River and Delaware Bay.
(G) One member who represents local fishing interests or an aquaculture Organization that depends on fisheries and resources of the Delaware River or Delaware Bay.
(H) Three members who represent environmental organizations active with respect to the Delaware River and Delaware Bay, including a watershed advocacy group and a wildlife conservation advocacy group.
(I) One member who represents an organization affiliated with recreational fishing interests in the vicinity of the Delaware River and Delaware Bay.
(J) Two members who are scientists or researchers associated with an academic institution and who have professional credentials in fields of research relevant to oil spill safety, oil spill response, or wildlife and ecological recovery.
(K) Two members who are municipal or county officials from Delaware.
(L) Two members who are municipal or county officials for New Jersey.
(M) Two members who are municipal or county officials from Pennsylvania.
(N) One member who represents an oil spill response organization located on the lower Delaware River and Delaware Bay.
(O) One member who represents the general public.

The DRBOSAC may also consist of an appropriate number (as determined by the Commandant of the Coast Guard) of non voting members who represent Federal agencies and agencies of the states of New Jersey, Pennsylvania, and Delaware with an interest in oil spill prevention in the Delaware River and Delaware Bay.

The members outlined in (A) can be either Special Government Employees or representatives. Members who are merely employed by port authorities shall be designated as SGEs and members that represent these port authorities shall be designated as representative members.

The members in paragraphs (B), (C), (D), (E), (F), (G), (H), (I), (K), (L), (M), (N) are representative members and not Special Government Employees as defined in section 202(a) of Title 18, United States Code.

The members in paragraphs (J) and (O) serve as a Special Government Employees as defined in section 202(a) of Title 18, United States Code.

The terms of office for members initially appointed to the Committee shall expire 18 months from the date of their appointment.

12. Subcommittees:

The DRBOSAC Chairperson may establish subcommittees for any purpose consistent with this charter subject to the approval of the DFO. Such subcommittees may not working dependently of the chartered Committee an authority to make decisions on behalf of the DRBOSAC and may not report directly to the Federal government or any other entity.

The Chair may appoint subcommittee members from either the Committee of the public. The subcommittee chair shall be a Committee member. The subcommittee shall be required to take minutes which shall contain a record of all persons present, a complete and accurate description of matters discussed and conclusions reached.

September 25, 2007
Agency Approval Date
October 1, 2007
GSA Consultation Date
October 1, 2007
Date Filed with Congress

Revised Charter (December 2010)

Authority:

Section 607 of the Coast Guard and Maritime Transportation Act of 2006, Public Law 109-241, as amended

Purpose:

The DRBOSAC provides advice, recommendations, and a ranking of priorities for measures to improve the prevention of and response to future oil spills in the Delaware River and Bay. Not later than December 31, 2010, it shall provide a report to the Commandant of the Coast Guard, the Governors of the States of New Jersey, Pennsylvania, and Delaware, the Committee on Commerce, Science, and Transportation of the Senate and the Committee on Transportation and Infrastructure of the House of Representatives, detailing those recommendations and priorities.

When this committee was authorized in 2006, the deadline for providing the report required in the above paragraph was 18 months after appointment of the committee's members, April 30, 2010. However, the committee did not complete its work by that date and, because the committee's authority terminated in April, has been unable to meet.

Charter Amendments:

Section 10. Duration, has been amended to reflect the new termination date of not later than December 31, 2010.

Additional amendments have been made to conform to the uniform charter format established for all DHS advisory committees.

Charter filing date:
Remains April 6, 2010.

UNITED STATES DEPARTMENT OF HOMELAND SECURITY

UNITED STATES COAST GUARD

DELAWARE RIVER AND BAY OIL SPILL ADVISORY COMMITTEE

1. Committee's Official Designation:
Delaware River and Bay Oil Spill Advisory Committee

2. Authority:
As provided for in section 607 of the Coast Guard and Maritime Transportation Act of 2006, Public Law 109-241 (as amended), this charter establishes the Delaware River and Bay Oil Spill Advisory Committee (DRBOSAC). This committee is established in accordance with, and operates under, the provisions of the Federal Advisory Committee Act (FACA) (Title 5, United States Code, Appendix).

3. Objectives and Scope of Activities:
The DRBOSAC provides advice, recommendations, and a ranking of priorities for measures to improve the prevention of and response to future oil spills in the Delaware River and Bay. Not later than December 31, 2010, it shall provide a report to the Commandant of the Coast Guard, the Governors of the States of New Jersey, Pennsylvania, and Delaware, the Committee on Commerce, Science, and Transportation of the Senate and the Committee on Transportation and Infrastructure of the House of Representatives, detailing those recommendations and priorities.

4. Description of Duties:
The duties of the DRBOSAC are solely advisory in nature.

5. Officials to Whom the Committee Reports:
The DRBOSAC provides advice and recommendations to the Secretary through the Commandant of the Coast Guard, Commander, Sector Delaware Bay, Commander, Fifth Coast Guard District and Commander, Atlantic Area.

6. Agency Responsible for Providing Necessary Support: The Department of Homeland Security shall be responsible for providing financial and administrative support to the committee. Within DHS, Sector Delaware Bay, United States Coast Guard will provide this support.

7. Estimated Annual Operating Costs and Staff Years:
The estimated operating cost of the DRBOSAC is $90,000.00, which includes 0.75 staff years of support.

8. Designated Federal Officer:
A full-time employee of the Coast Guard is appointed by the Director of Response Policy (CG-53) as the DRBOSAC Designated Federal Officer (DFO). The DFO or the alternate DFO approves or calls DRBOSAC meetings, approves meeting agendas, attends all committee and subcommittee meetings, adjourns any meeting when the DFO determines adjournment to be in

the public interest, and chairs meetings when directed to do so by the Director of Response Policy.

9. Estimated Number and Frequency of Meetings:
Meetings of the DRBOSAC may be held with the approval of the DFO; it is expected the committee will meet twice a year. Members may be reimbursed for travel and per diem expenses, and all travel for DRBOSAC business must be approved in advance by the DFO. Committee meetings are open to the public unless a determination is made by the appropriate DHS official, in accordance with DHS policy and directives, that the meeting should be closed in accordance with Title 5, United States Code, subsection (c) of section 552b.

10. Duration:
The DROBOSAC shall terminate 30 days after it transmits its report, pursuant to Section 3 of this charter, but no later than December 31, 2010, whichever is earlier.

11. Member Composition:
The DRBOSAC shall consist of 27 voting members who are appointed by and serve at the pleasure of the Commandant of the Coast Guard, and who have particular expertise, knowledge, and experience regarding the transportation, equipment, and techniques that are used to ship cargo and to navigate vessels in the Delaware River and Bay, as follows:

(A) Three members who are employed by port authorities that oversee operations on the Delaware River or have been selected to represent these port authorities, of whom--
  (i) one member shall be an employee or representative of the Port of Wilmington;
  (ii) one member shall be an employee or representative of the South Jersey Port Corporation; and
  (iii) one member shall be an employee or representative of the Philadelphia Regional Port Authority.

(B) Two members who represent organizations that operate tugs or barges that utilize the port facilities on the Delaware River and Delaware Bay.

(C) Two members who represent shipping companies that transport cargo by vessel from ports on the Delaware River and Delaware Bay, of whom at least one may not be a representative of a shipping company that transports oil or petroleum products.

(D) Two members who represent operators of oil refineries to the Delaware River and Delaware Bay.

(E) Two members who represent State-licensed pilots who work on the Delaware River and Delaware Bay.

(F) One member who represents labor organizations whose members load and unload cargo at ports on the Delaware River and Delaware Bay.

(G) One member who represents local commercial fishing interests or an aquaculture organization, the members of which organization depend on fisheries and resources of the Delaware River or Delaware Bay.

(H) Three members who represent environmental organizations active with respect to the Delaware River and Delaware Bay, including a watershed advocacy group and a wildlife conservation advocacy group.
(I) One member who represents an organization affiliated with recreational fishing interests in the vicinity of the Delaware River and Delaware Bay.
(J) Two members who are scientists or researchers associated with an academic institution and who have professional credentials in fields of research relevant to oil spill safety, oil spill response, or wildlife and ecological recovery.
(K) Two members who are municipal or county officials from Delaware.
(L) Two members who are municipal or county officials for New Jersey.
(M) Two members who are municipal or county officials from Pennsylvania.
(N) One member who represents an oil spill response organization located on the lower Delaware River and Delaware Bay.
(O) One member who represents the general public.

The DRBOSAC may also consist of an appropriate number (as determined by the Commandant of the Coast Guard) of non-voting members who represent Federal agencies and agencies of the States of New Jersey, Pennsylvania, and Delaware with an interest in oil spill prevention in the Delaware River and Delaware Bay.

The members outlined in (A) can be either Special Government Employees or representatives. Members who are merely employed by port authorities shall be designated as SGEs and members that represent these port authorities shall be designated as representative members. The members in paragraphs (B), (C), (D), (E), (F), (G), (H), (I), (K), (L), (M) and (N) are representative members and not Special Government Employees as defined in section 202(a) of Title 18, United States Code.

The members in paragraphs (J) and (O) serve as a Special Government Employees as defined in section 202(a) of Title 18, United States Code.

The terms of office for members initially appointed to the committee shall expire upon termination of the committee or December 31, 2010, whichever occurs first. A member appointed to fill an unexpired term serves the remainder of the term.

12. Officers

The Committee elects by majority vote one member of the committee to serve as Chair and one member as Vice-Chair. The Vice-Chair will act as Chair in the absence of or incapacity of the Chair or in the event of a vacancy in the office of the Chair. The term of office for the Chair and Vice-Chair shall expire upon termination of the committee or December 31, 2010, whichever occurs first.

13. Subcommittees:

The DFO may establish subcommittees for any purpose consistent with this charter. Such subcommittees may not work independently of the chartered committee and must present their work to the DRBOSAC for full deliberation and discussion. Subcommittees have no authority to

make decisions on behalf of the DRBOSAC and may not report directly to the Federal government or any other entity. The subcommittee chair shall be a DRBOSAC member.

14. Recordkeeping:
The records of the DRBOSAC, formally and informally established subcommittees, or other subgroups of the committee, are handled in accordance with General Records Schedule 26, Item 2 or other approved agency records disposition schedule. These records are available for public inspection and copying, in accordance with the Freedom of Information Act (Title 5, United States Code, section 552).

15. Filing Date:
April 6, 2010
Department Approval Date
March 2, 2010
CMS Consultation Date

Appendix B – Significant* Oil Spill Events in Delaware River and Bay

Responsible Party	Date	Amount Spilled	Product Spilled
M/T *Elias* – ARCO, Ft. Mifflin Dock	9 April 1974	12,000 bbl of a 217,000 bbl cargo	***Bachaquero crude oil explosion, fire, spill
T/V *Corinthos* – Marcus Hook	31 Jan 1975	266,000 barrels	Fire and crude oil spill while docked at BP *Edgar M. Queeny* collided with *Corinthos*
T/V *Grand Eagle*	29 Sept 1985	435,000 gallons	Crude oil **-** grounded MH Bar
Coastal Eagle Point	5 Dec 1985	22,000 gallons 80 tons	Benzene
Standard Chlorine	3 Jan 1986	569,000 gallons	PDCB/benzene
T/V *Intermar Alliance*	21 Mar 1986	189,000 gallons	Nigerian/Ninian Crude loss of steerage
T/V *Viking Osprey*	8 Sept 1986	295,000 gallons	Bottom scrap Marcus Hook Bar –Claymont Shoal
M/V *Jahre Spray*	7 Oct 1988	Trailing sheen - 6 miles	Nigerian crude oil
T/V *Presidente Rivera* –South of Marcus Hook	24 June 1989	435,000 gallons	#6 heavy oil – industrial grade – grounding Claymont Shoal
****T/V *Exxon Valdez***	24 March 1989	10.8 million gallons	North Slope crude oil
Barge *Worlds Radiance* – Hogg Island Terminal	21 Nov 1989	4200 gallons	Storm - Barge broke from dock while off loading – crude oil
T/V *Faith I & Ocean Barge 190*	19 Aug 1990	168,000 gallons	Gasoline **-** collision
M/V *Santa Clara* 30 miles off Cape May	3 Jan 1992		Arsenic Trioxide –containers weather
M/V *Kentucky*	22 July 1994	13,000 gallons	Crude oil – suspected grounding Marcus Hook bar-Claymont Shoal
M/V *Jahre Spray* Eagle Point Refinery	22 July 1995	56,000 gallons	West African Rabbi crude –transfer hose broke during storm
T/V *Anitra* Big Stone Anchorage	9 May 1996	42,000 gallons	Nemba and Cabinda light crude oils. Leak below water line.
Bouchard *Barge 155* Bombay Hook Anchorage	24 Oct 1996	2,000 gallons	#6 fuel from Anchor compartment while waiting out storm

T/V *Niki* - Delaware City	1996	1,500 gallons	
M/V *Mystras* - Big Stone Anchorage	18 Sep 1997	200 bbls (8,400 gallons)	Brent crude oil
Bouchard *Barge #115*- Motiva	27 Oct 1999	6,300 gallons	Vacuum gas oil - overfill
Conectiv/IRPP	Dec 1999	750,000 gallons	subsurface diesel spill
Tug John Terecamo Near Ft. Mifflin	15 June 2001	2,000 gallons	Hit by propeller of Tanker –grounded to avoid sinking. Diesel fuel
Motiva Acid Spill Delaware City	17 July 2001-	Land based spill- 10,000 gallons to water	Spent sulfuric acid and water mixture – fire/explosion
T/V *Athos I* – Vicinity of CITGO docks, Paulsboro. NJ	26 Nov 2004	265,000 gallons	Crude oil – heavy Hit submerged objects
M/V *Bermuda Islander*	26 April 2006	Original mystery spill- ? gals	Oil trailing six miles
IPC Spill- Christina River, Wilmington	15 July 2006	2,100 gal	Waste oil – land based tank/line leak
T/V *Tigani* CITGO Dock	7 Oct 2007	1,600 gallons	#6 Bunker C oil – cracked scupper line that passed through a bunker tank – leaking while docked
Sunken Tugs - Schuylkill River	29 July 2008	1,200 gallons?	fuel oil/waste oil spill

*"Significant" is a relative term that is used in the title to mean amount spilled, level of response or the notoriety of the event.
**Exxon Valdez listed for comparison

***The petroleum industry generally classifies crude oil by the geographic location it is produced in (e.g. West Texas Intermediate, Brent), its API (American Petroleum Institute) gravity (an oil industry measure of density), and by its sulfur content. Crude oil may be considered *light* if it has low density or *heavy* if it has high density; and it may be referred to as sweet if it contains relatively little sulfur or *sour* if it contains substantial amounts of sulfur.

Brent and Ninian crude come from the North Sea area. Nemba and Cabinda light crude oils are produced in Angola. Nigerian crude oil could be Bonny Light, Agbami (light, sweet), Escravos or Pennington. Bachaquero crude oil is from Venezuela.

ACKNOWLEDGEMENTS

Ecosystem Management & Associates, Inc. and the sponsors of this project extend their thanks to all those who participated in the risk assessment workshops. Special recognition is extended to Mr. Gerald Conrad (USCG Sector Delaware Bay), who served as the Assessment Coordinator, and to CDR Team Deal (USCG Sector Delaware Bay), Martha Doyle (Partnership for the Delaware Estuary), Mr. Ed Levine and Mr. Gary Ott (NOAA HazMat Scientific Support Coordinators), Mr. Michael Chezik (US Department of the Interior), Mr. Bennett Anderson (Delaware Department of Natural Resources and Environmental Conservation) and Mr. David Sweeney (NJ Department of Environmental Protection), who served as the Assessment Planning Team, and to Dr. Alan Mearns (NOAA HazMat) for his support at the workshop and Dr. Glen Watabayashi (NOAA HazMat) for his help with oil fate modeling. Contractor support to assist in the planning and facilitation of the workshops and in the preparation of the report was provided by the Office of Incident Management and Preparedness, Headquarters, USCG (G-RPP) under Task Order HSCG23-05-J-MER193, issued under Contract Number DTCG23-03-D-MER148A. The support and guidance of the Project Manager, LCDR Mark Cunningham, and of LCDR Paul Lattanzi (his replacement) of G-RPP is gratefully acknowledged.

Ecological Risk Assessment: Consensus Workshop

Environmental Tradeoffs Associated With Oil Spill Response Technologies

Delaware Bay

Executive Summary

In January/February 2006, the United States Coast Guard (USCG) Sector Delaware Bay sponsored a workshop whose purpose was twofold: First, in response to the M/VAthos 1 oil spill in November 2004 and the ongoing work of the Area Committee, the USCG sought to bring together and educate the various non-spill response resource managers and scientist in the Delaware Estuary. Secondly, the workshop allowed the participants the opportunity to evaluate the relative risk to natural resources from various oil spill response options (on-water mechanical recovery, dispersant application, and on-shore mechanical recovery) compared to natural recovery.

The spill scenario designed by the Area Committee involved a release of approximately 60,000 gallons of Nigerian Qua Iboe crude oil due to an accident in the main channel of the upper estuary. The hypothetical date for the spill was mid-May. This period was selected to incorporate possible impacts to signature estuary species. During this period of time large populations of migratory shorebirds would be present in the estuary and Horseshoe Crab spawning would be occurring.

The workshop consisted of two three-day sessions, separated by approximately one month. Over 50 agency, academic and NGO personnel participated over the 6 day period. At the initial meeting in January, five focus groups were established and analyzed natural recovery and on-water mechanical recovery. At the second workshop in February, due to prior commitments and a spill in New Jersey, attendance was reduced and only three focus groups (including some participants from the two disbanded groups) were maintained; at that time the remaining three alternatives were ranked.

After evaluating the various spill response options within the parameters presented for this scenario the groups came to the consensus that the most benefit to the environment occurred with dispersant use, if the dispersant application was highly effective (85% removal). However, the groups questioned how realistic this scenario would be considering all the variables affecting a dispersant's effectiveness, e.g., weather, temperature, sea state, spill product, logistics of dispersal, time constraints, dispersant availability and supply, water depth, circulation patterns and flushing rates, natural resources, etc. When considering a more realistic effectiveness ranges within 35-50% the benefits of dispersant use, in this

scenario, are not quite as dramatic and overwhelming as the original 85% effectiveness rating.

Primary risks noted by all groups, to shore birds, waterfowl and Horseshoe Crabs on the water surface and along the shoreline, were all reduced in that case. Concerns were voiced regarding the increase over exposure of water column organisms to dispersed oil. This concern was less than the risk perceived to the other resources.

Overall, the participants felt that the ERA was a very valuable exercise. A list of recommendations was developed and is included at the end of this report. These recommendations will be reviewed by the Area Committee for further action. It was also strongly recommended that the USGC/Area Committee should consider sponsoring additional ERA's to examine other critical scenarios in other parts of the Estuary.

1.0 Objectives of the Delaware Bay Workshop

1.1 Background and Process

In 1998, the United States Coast Guard (USCG) began sponsoring efforts to develop a comparative risk methodology to evaluate oil spill response options. Interest in selecting response options based on a risk/benefit analysis predates the 1998 initiatives, but the current effort is different in that it emphasizes a consensus-building approach to evaluate risks and benefits.

Headquarters, USCG (G-MOR) sponsored the development of a guidebook on this process. The document, *Developing Consensus Ecological Risk Assessments: Environmental Protection in Oil Spill Response Planning. A Guidebook*, is available from G-MOR (Aurand et al., 2000). It can also be downloaded from the contractor's web site at www.ecosystem-management.net.

The process is designed to help planners compare ecological consequences of specific response options, especially in nearshore or estuarine situations. This is particularly important for consideration of dispersants and in-situ burning, which present difficult analytical issues. The process focuses on ecological "trade offs" or cross-resource comparisons. Through a structured analytical approach participants find "common ground" for evaluating impacts and they develop defensible logic to support their conclusions. The process is consistent with the U.S. Environmental Protection Agency's (EPA) Ecological Risk Assessment (ERA) guidelines (U.S. EPA, 1998), but emphasizes development of group consensus among stakeholders. The process uses a series of analytical tools specifically developed for use in a group environment. It is designed as a planning tool and should not be used during an actual event. However, knowledge gained by participants in the consensus-building process facilitates real-time decision-making.

Training usually involves two 2- or 3-day workshops lead by a facilitator. The ideal size is 25 to 30 participants, including spill response managers, natural resource managers and trustees, subject matter experts, and non-governmental organizations. The goal is to achieve consensus interpretations of potential risks and benefits associated with selected response options based on a scenario developed by local participants. Time between the two workshops is used by participants to research issues of concern before developing final conclusions. The process focuses heavily on achieving a consensus interpretation of the available technical information. Therefore, it is important to have broad stakeholder representation in the decision process; otherwise, results may not be accepted by all stakeholders involved in an actual spill event.

The workshop process includes three primary phases - **problem formulation, analysis,** and **risk characterization**. Details of the process are described in the Guidebook. In the first phase, **problem formulation**, participants develop a scenario for analysis, identify resources of concern along with associated assessment thresholds, and prepare a conceptual model to guide subsequent analysis. In the **analytical phase**, participants characterize exposure and ecological effects. The conceptual model, developed in the problem formulation phase, directs the analysis using standard templates and simple analytical tools that define and summarize the analysis for each resource of concern and each response option. Finally, participants complete a **risk characterization**. During this phase,

participants interpret their results in terms of the costs and benefits of each response option to overall environmental protection as compared with natural recovery (i.e., baseline).

1.2 Sponsor's Objectives

The Delaware Bay workshop was sponsored by the Sector Delaware Bay Area Committee. The objectives of the meeting were to improve oil spill response strategies and enhance existing oil spill contingency planning in the area through open consultation between oil spill planners, managers, responders and resource trustee agencies. Through the consensus ERA process, the sponsors hope to facilitate a better understanding of resource trustee and response agency concerns, more timely and effective response decisions, and greater resource protection and recovery in the event of future oil spills.

1.3 Participants

A total of 48 individuals from 21 organizations attended the first workshop, with lesser numbers at the second session. Their names and affiliations are included in Appendix A. At the first workshop in January the participants were divided into five focus groups. At the second workshop in February, Focus Groups 2 and 4 were not well-represented, and the individuals from those groups joined Focus Group 1, 3 or 5. A significant portion of the reduction in attendance was due to an actual spill in New Jersey. Some persons had also indicated early in the process that they would only be able to attend the first session. The periods attended by each participant, and the focus groups they participated in are all indicated in Appendix A.

1.4 Organization of the Report and the Associated Compact Disk

This report is one of a series of files on a Compact Disk (CD) prepared as a project deliverable product. The report summarizes the results of the workshops, and presents the conclusions of the participants. It is formatted to be printed as an independent, double sided report. In addition, the CD contains copies of some of the presentations made at the workshops by the sponsors or by subject matter experts, as well as copies of documents provided as reference material by the sponsors. These files are cited at appropriate locations in the text of the report.

2.0 Overview of Workshop Events

This training exercise consisted of two 3-day workshops. The first workshop was held from 11 to 13 January, and the second from 14 to 16 February, 2006.

At the first workshop the meeting began with an overview of the ERA process (see ERA Overview on the workshop CD) followed by a discussion of the information developed prior to the meeting by the Steering Committee concerning the scenario, the resources at risk, and the response options to be considered (Problem Formulation Phase). This included a presentation by Dr. Alan Mearns, National Ocean and Atmospheric Administration (NOAA), Hazardous Materials Response Division (HazMat) which summarized the key elements of the scenario and the results of the NOAA trajectory modeling using the General NOAA Modeling Environment (GNOME) model and the Automated Data Inquiry for Oil Spills (ADIOS) model (see the Oil Spill Scenario file[1] and the Surface Oil Trajectory file on the workshop CD). The Steering Committee recommended that the group evaluate four response options, natural recovery (necessary as an analytical baseline), on-water mechanical recovery, use of dispersants, and on-shore mechanical recovery.

Since protective booming is a primary component of current response planning in Delaware Bay, the group discussed how that was to be considered.[2] Several options were presented. The Steering Committee considered the options and concluded that for natural recovery it would be assumed that no booming would occur, but for all other options protective booming would be in place. Since the GNOME model does not really account for the amount of oil entering the tidal creeks, the effect of booming will have to be done qualitatively by each focus group during their evaluation. This is a key assumption, because preventing contamination of marshes along the tributaries will reduce the level of concern.

The inclusion of an additional response option, on-shore in-situ burning, was discussed as well. The participants agreed to defer a decision on this until the second workshop, when it would be possible to better determine if sufficient time was available to complete an evaluation.

The participants then discussed the draft resources at risk matrix prepared by the facilitators and reviewed by the Steering Committee. There was a discussion about the value of adding salt marsh impoundments as a category, but it was decided that the tide gates would be closed during an oil spill and so they did not need to be added. Marine habitat was defined as the area beyond a line connecting Cape May and Cape Henlopen, while estuarine habitat was inside of that line. There was considerable discussion as to the water depth at which “shallow” and “deep” habitats should be divided, since Delaware Bay is quite shallow. Ultimately, the participants accepted the original suggestion to separate the two at a depth of 20 feet, based on the likely depth that dispersed oil concentrations were likely to be a concern.

[1] The “Oil Spill Scenario” PowerPoint presentation includes the basic information on the oil spill, as well as a summary of the results of the trajectory and weathering analyses for the surface slick alone, and for the use of dispersants at an effectiveness of 85%. The dispersant use portion was not presented until the third day of the first workshop, at the beginning of the evaluation of the dispersant option.

[2] Protective booming involves the use of specially designed boom along the shoreline or across the mouths of inlets, bays or tidal streams to deflect oil away from sensitive shoreline habitats. The use of such boom to prevent oil from entering tidal creeks in Delaware Bay is a key element in existing plans, and significant quantities of such boom is pre-positioned as well as stockpiled by oil spill response organizations in the region.

Several other minor changes to the draft habitat list and the characteristic species listing were proposed and accepted.

Dr. Aurand (facilitator, EM&A) then reviewed the concept of "thresholds" with the participants, and suggested that the criteria listed on the "Final Thoughts on Thresholds" slide in the ERA process briefing offered conservative guidance for their discussions later in the process. There were no objections. The guidelines were as follows:

- Organisms (birds, turtles, marine mammals) on the water surface should be considered affected if they are likely to be in contact with sheen.
- Shoreline habitat should be considered to be affected if there is between 10 to 100 grams of oil or emulsified oil per square meter.
- Organisms in the water column can be evaluated by the criteria presented in Table 4.1.
- If necessary, sediment exposure effects can be based on the NOAA Screening Quick Reference Tables (SQuiRTs) (NOAA, 1999).

Discussions then moved on to the risk ranking matrix. The final matrix is presented as Figure 4.1. As part of the risk ranking discussion, the participants agreed that the definitions they would use for the different levels of population baseline units would be local (L), which meant the population was essentially restricted to Delaware Bay; regional (R) which meant the population was restricted to the Mid-Atlantic area, and national/international (N) for broader populations.

The second day began with a review of the discussions of Day 1. Some additional, minor changes were made to the resources at risk table, and the issue of where to divide shallow and deep habitat was again raised, with some participants suggesting that it might be useful to divide the less than 20-foot habitat into 0 to 10 feet and 10 to 20 feet. It was agreed that this could be discussed in the focus groups, but that the table would use the 20-foot demarcation. Dr. Aurand then gave an overview presentation on oil spill basics. Following that presentation, the participants were divided into focus groups (see Appendix A) and began the risk assessment process for natural recovery.

On day three the focus groups completed and discussed the risk scoring for natural recovery and on-water mechanical recovery, and began work on the dispersant use option. Prior to beginning consideration of any of the response options under review, Dr. Aurand, presented an overview of response options.[3] The on-water mechanical recovery discussions were preceded by a presentation by Mr. Eugene Johnson, Delaware Bay and River Cooperative, Inc. on available resources and recovery strategies for the Delaware Bay (see On-Water Recovery on the workshop CD). The participants agreed, after significant discussion, to use an effectiveness of 25% for on-water mechanical recovery. After the focus groups completed their review of on-water mechanical recovery, Dr. Aurand gave an introduction to dispersants. He was followed by Dr. Alan Mearns, who reviewed the results of the GNOME and ADIOS modeling for dispersant use at an assumed effectiveness of 85%

[3] The presentations "Overview of Response Options" and "Introduction to Dispersants" are part of a dispersant training course that is offered by EM&A. More information on these presentations may be obtained by contacting EM&A directly.

(see the Dispersant at 85% Surface Oil Shown and Dispersant at 85% No Surface Oil[4] files on the workshop CD). There was a great deal of discussion concerning the realism of the 85% effectiveness option. The facilitation team explained that it was not meant to imply that it was expected to be achieved, but rather to allow the analysis of a "worst case" situation for water column exposure. After questions and answers, the focus groups had approximately one hour to consider the dispersant option.

All of the groups successfully ranked natural recovery and on-water mechanical recovery, but did not complete the evaluation of the consequences of dispersant use. At the end of the session, they developed a list of items to be addressed at the beginning of the second workshop:

- Participants want information/presentation on current dispersant policy.
- Participants would like to see another percentage of effectiveness (35% modeling run); also loading rate data for shoreline impacts for all three scenarios.
- Is there more information on aquatic amphipods, mollusks, etc. – in general, what are they and what is their function within the environment?
- May be useful to show a foodweb (direct, indirect) for this system for this time of year (Living Resources of the Delaware Estuary – bring a copy for each participant).
- If there were a proposed change on dispersant use policy, what process would be used to approve it?
- Have five hard copies of the Environmental Sensitivity Index for the next workshop.
- Bring additional toxicity data (if available) on species and/or information on natural bioavailability at or in the benthic environment and in the water column.
- Provide the quantity of dispersed oil entering the Broadkill and Liepsic Rivers.
- Participants should review the current Delaware Bay Area Contingency Plan prior to the next meeting.
- Get information on dispersed oil impacts at the molecular level on Horseshoe Crab eggs.
- Bring toxicity data on oil and dispersed oil biouptake by polychaetes.

In addition, the participants noted that the risk from this scenario was serious (based on the season and trajectory) for what was a relatively small spill, and that it really presented a challenge to decision-makers based on the risks to shorebirds and Horseshoe Crab eggs. The participants recommended considering other scenarios (seasonality, different oils, and/or different locations) if possible.

After introductions, the second workshop (14-16 February) began with a movie entitled "Introduction to Dispersants and Their Application," prepared by Oil Spill Response Limited (OSRL). This was followed by a presentation by Drs. Aurand and Coelho (facilitators, EM&A) which addressed many of the questions raised at the end of the first workshop (see the Additional Data file on the workshop CD). This was followed by a

[4] At the workshop, only the first of these files was available, but it was difficult to see the dispersed oil trajectory, so the second file, which does not show the oil remaining on the surface was developed for inclusion in the CD.

presentation by Mr. Gerald Conrad on the current dispersant policy in the Delaware Bay. The policy is available in the Sector Delaware Bay Area Contingency Plan, which is available at two internet locations. These are the USCG Sector Delaware Bay website at http://www.uscg.mil/d5/sector/delawarebay/Area_Committee.htm and the USCG Homeport website, http://homeport.uscg.mil/mycg/portal/home/do. He indicated that the ERA process will not directly result in any reconsideration or changes in policy, but that the issues being discussed are very important for future planning. If there were to be changes, there would need to be a formal consideration by the Sector Delaware Bay Area Committee, which would include extensive coordination and environmental review by both state and federal agencies. The current program for dispersant use monitoring was also discussed by Mr. Ben Anderson (also available in the Sector Delaware Bay Area Contingency Plan).

It should be noted that there was an oil spill incident in New Jersey which prevented a number of participants from attending and caused several others to leave early on the first day. This led to a decision to consolidate the remaining participants into three groups, since most of the missing participants were from two of the original groups. These changes are described in Appendix A (Participants). In Section 4, the results for all five groups are shown for natural recovery and on-water mechanical recovery, which were the two options scored in the first workshop. Results for dispersants and on-shore mechanical recovery are shown only for focus groups one, three and five (which had the additional members at meeting two).

Dr. Alan Mearns then presented the GNOME and ADIOS results for the use of dispersants at 35% effectiveness (see the Oil Spill Scenario 2[5], Dispersant at 35% Surface Oil Shown and Dispersant at 35% No Surface Oil files on the workshop CD). He also reviewed the results of the surface oil trajectory analysis and the evaluation of dispersant use at 85% effectiveness for a comparison. When this was completed, the participants were asked if they wanted to score dispersants at both effectiveness levels, or just one. The group chose to score both. The remainder of day one was spent with the focus groups completing the evaluation of the dispersant option.

Day two opened with a review of the results for natural recovery, on-water mechanical recovery, and dispersant use (35% and 85% effectiveness). The participants reviewed and discussed the differences between the various focus groups, and why they might have occurred. In general, however, there was good agreement between the three remaining groups. This was followed by an introduction to shoreline recovery by Dr. Aurand, and a presentation on shoreline recovery in the Delaware Bay area by Mr. Pat McGovern of Clean Venture, Inc. (see Delaware Bay Shoreline Recovery on the workshop CD). Dr. Alan Mearns also reviewed the results of a bioremediation study conducted on Slaughter Beach in the mid-1990s. The participants decided, based on Dr. Mearn's presentation, that they did not need to consider bioremediation in this workshop. Participants then discussed the effectiveness of shoreline recovery, and decided that it would not be possible to select one value to use in the analysis. Participants were reminded that protective booming should be assumed during the evaluation. The participants completed their review of on-shore mechanical recovery prior to lunch.

The remainder of day two was spent discussing possible ways to address other scenarios and/or the critical factors in the scenario which they just completed. There was support for considering the effects of a larger spill, a different product, a different season, and

[5] This presentation includes the information on dispersant use at 35% effectiveness, as well as many of the same slides used in the original presentation at the first workshop.

a location further up into the Delaware River. A number of participants felt, however, that we could not do justice to such discussions without a comprehensive scoring, and there was not sufficient time remaining to do that. A decision was made by the Steering Committee to have the three focus groups meet individually for approximately 1.5 hours to have open discussions about the key factors in their analysis and to develop a list of items they would like to share with the group. The focus groups were told to consider the following two questions:

- What were the 'drivers' that affected your decisions in this scenario?
- How would changes in those areas change your conclusions?

Day two ended with the participants reviewing the results of their discussions, which are presented in Section 5.1

Day three was a half-day session devoted to a discussion of recommendations and conclusions. These are presented in Section 5.2.

3.0 Exercise Scenario and Basic Analytical Information

3.1 Exercise Scenario

After considering a variety of options, the Steering Committee developed a scenario which threatened both the Delaware and New Jersey shorelines. This was done by changing the wind direction partway through the scenario. There was no narrative scenario developed, but the summary spill conditions are presented in Table 3.1. The weather conditions are within normal ranges for spring, and the volume released is consistent with a collision or grounding leading to a partial loss of cargo (one compartment on a larger vessel). Nigerian Qua Iboe crude oil is a commonly transported oil in the Delaware Bay, and it was tested and found to be dispersible by NOAA prior to the workshop. This information was presented to the participants on the first day for review and accepted. The participants felt that the scenario represented serious risk to natural resources, and really challenged the managers to discuss the risks to shore birds and breeding Horseshoe Crabs.

Table 3.1 Key Parameters for the Delaware Bay Scenario.

Time/Date	0600 on 20 May 2006
Location	39º15.66 N 75º20.33W
Volume	60,000 gallons (1432 barrels)
Oil Type	Nigerian Qua Iboe
Specific Gravity	API 36.2
Wind Speed	10 to 15 knots (variable directions)
Air/Water Temperature	15º C

3.2 Geographic Area of Concern

The general area of concern was the Delaware Bay south of the spill site, and the open ocean waters immediately adjacent to the mouth of the Bay. The approximate extent of the area is defined by the extent of the map in Figure 3-3, which shows the surface oil trajectory. The area includes all of Delaware Bay and its shoreline south of the release point, as well as the ocean area and associated shoreline immediately adjacent to the mouth of the Bay.

3.3 Resources of Concern

Participants reviewed and agreed to use the resource table developed by the facilitators for the Steering Committee prior to the meeting with minor modifications to the list of representative species, and some changes to the proposed habitats and subhabitats. The final table is presented in Appendix B. The major discussion items and their resolution were:

- Delaware salt marshes contain a large number of impoundments, which could be contaminated. Participants agreed to assume that tidal access (via tide gates) could be shut off during an oil spill, so that contamination would not occur.
- Marine habitat was defined as the area outside of a line connecting Cape May and Cape Henlopen. The bay is the area inside of the Capes.
- The category "Structured Hard Bottom Community" on the table refers to non-oyster communities, and includes sabellid reefs, dense clam or mussel beds, and artificial reefs.
- The issue of listing protected species as a separate category on the table was discussed and the participants agreed that it was unnecessary, based on the proposed ranking system (impacting such a species leads to a high percentage impact and/or long recovery, resulting in a high risk).
- There was considerable discussion as to whether or not a depth of 20 feet was the appropriate level at which to divide "shallow" and "deep" subtidal and water column communities. Since Delaware Bay has extensive areas which are less than 20 feet deep, there was some interest in having an area of 0-10 feet and then an area of 10-20 feet in depth. Ultimately, the one area was used, and the participants were instructed to discuss the issue in their focus groups, and to add comments to the ranking score if it proved to be critical to their discussions.

3.4 Conceptual Model

During discussions about the general analytical process, the participants agreed that developing a detailed conceptual model was not necessary for their purposes. As an alternative, they accepted the list of seven hazards developed initially in a detailed conceptual model prepared for the San Francisco Bay workshop (Pond et al., 2000) that have been used in all subsequent workshops. They agreed that these should be considered for each of the proposed response options (these hazards are air pollution, aqueous exposure, physical trauma, oiling/smothering, thermal, waste and indirect). The response options to be considered would be natural recovery (no response), on-water mechanical recovery, dispersant application, on-shore mechanical recovery and, if time was available, on-shore in-situ burning.

3.5 Modeling Results

The NOAA HazMat Modeling Group used the basic information in the scenario to develop a surface trajectory and a dispersed oil trajectory analysis using GNOME for the detailed risk assessment portion of the workshop. Basic weathering information was calculated using the ADIOS II program. Mass balance estimates are presented in Tables 3.2

(oil only) and 3.3 (emulsified oil) and in Figures 3.1 and 3.2. This oil (Nigerian Qua Iboe crude oil) emulsifies quite rapidly, but is dispersible early in the spill. The volume present in the environment more than doubles in twelve hours and ultimately more than 300,000 gallons of mousse are present, which is six times the volume that was originally released. Table 3.4 shows the volume of oil and emulsion present on six shoreline segments if no response options are implemented.

Table 3.2 Oil Budget (in Gallons) Budget for Undispersed and Dispersed Oil (35 and 85% Effectiveness) as Predicted in the Delaware Bay Scenario, Initial Spill Volume 60,000 Gallons.

Oil in the Environment, 24 Hours Post-spill				
Response	Floating	Beached	Dispersed	Evaporated
No Dispersal	24,348	6,804	4,656	24,192
Disperse 35%	15,444	4,692	17,688	22,176
Disperse 85%	3,516	1,116	36,024	18,344
Oil in the Environment, 48 Hours Post-spill				
Response	Floating	Beached	Dispersed	Evaporated
No Dispersal	22,080	7,944	4,656	25,320
Disperse 35%	14,172	5,352	17,688	22,788
Disperse 85%	3,072	1,356	36,024	19,548

Table 3.3 Water-in-oil Emulsion (Mousse) and Oil Budget (in Gallons) for Undispersed and Dispersed Oil (35 and 85% Effectiveness) as Predicted in the Delaware Bay Scenario, Initial Spill Volume 60,000 Gallons, 89.9% Emulsification in 30 Hours.

Emulsion in the Environment, 24 Hours Post-spill			
Response	Floating	Beached	Total Emulsion
No Dispersal	183,068	51,158	234,226
Disperse 35%	116,120	35,278	151,398
Disperse 85%	24,902	8,391	33,293
Emulsion in the Environment, 48 Hours Post-spill			
Response	Floating	Beached	Total Emulsion
No Dispersal	218,614	78,653	297,267
Disperse 35%	140,317	52,990	193,307
Disperse 85%	30,059	13,426	43,485

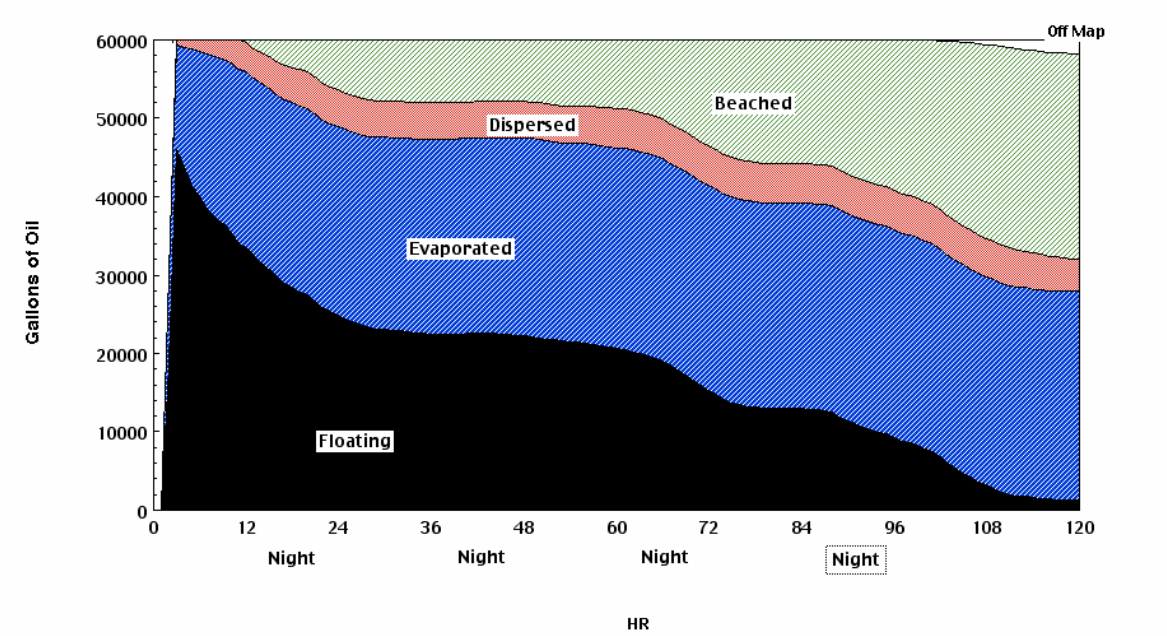

Figure 3.1 *The ADIOS predictions for the fate of the floating oil (emulsification not considered) in the Delaware Bay scenario if no response options are employed.*

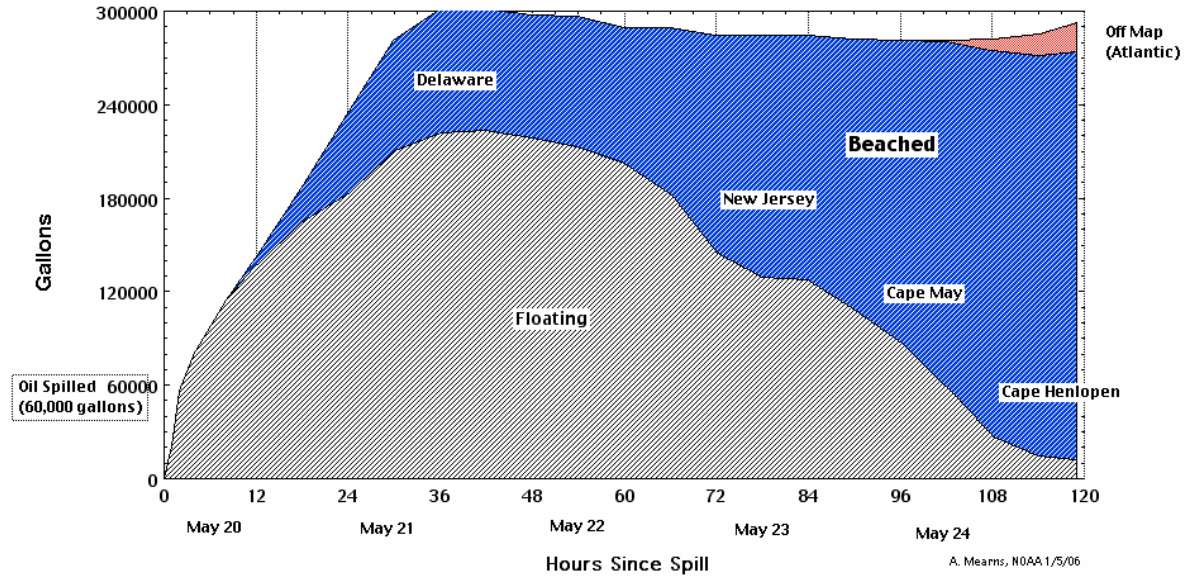

Figure 3.2 *The ADIOS predictions for floating and beached oil when emulsification is considered in the Delaware Bay scenario if no response options are employed.*

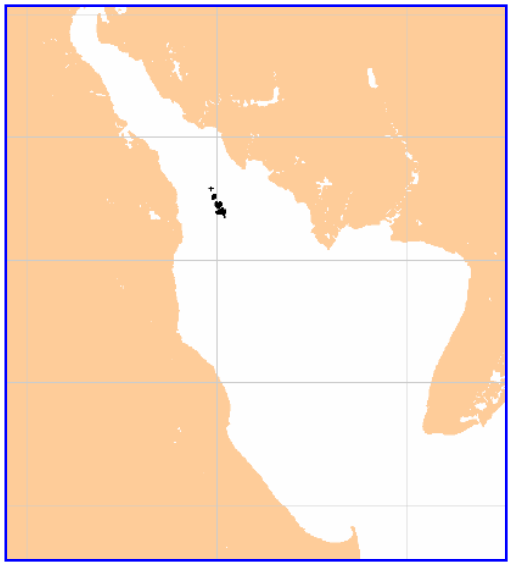
Selected snapshots from the surface oil trajectory modeling results are shown in Figure 3.3. The average concentration in the dispersed oil plume produced without the use of dispersants (Figure 3.4, at an expanded scale) is compared to toxicity threshold values for adult crustaceans (Figure 3.5) and sensitive life history stages (Figure 3.6) (see Table 4.1 and the associated discussion in Section 4 for information on development and interpretation of thresholds). Figure 3.7 presents the same data as in Figure 3.6, but at an expanded scale in order to clarify the relationship between thresholds and observed concentrations.

While the movement of the floating oil is heavily influenced by tidal flow, wind is the primary mover for surface oil. Under the modeled wind conditions the oil initially moves towards the Delaware shore, in the vicinity of Bombay Hook and further south. After approximately 30 hours the wind changes and the slick moves towards the New Jersey shore, stranding from the vicinity of Fortescue, NJ all the way to Cape May. Finally, after approximately three days the remaining floating oil leaves Delaware Bay and moves south along the Atlantic coast. The volumes of oil (or emulsion) present in several locations are given in Table 3.4. Given the volume of the initial spill, the volumes of emulsion which strand near Bombay Hook, DE and Cape May, NJ are quite large, and there is also considerable volume inside the hook of Cape Henlopen, DE as well as south of Cape Henlopen along the Atlantic shore.

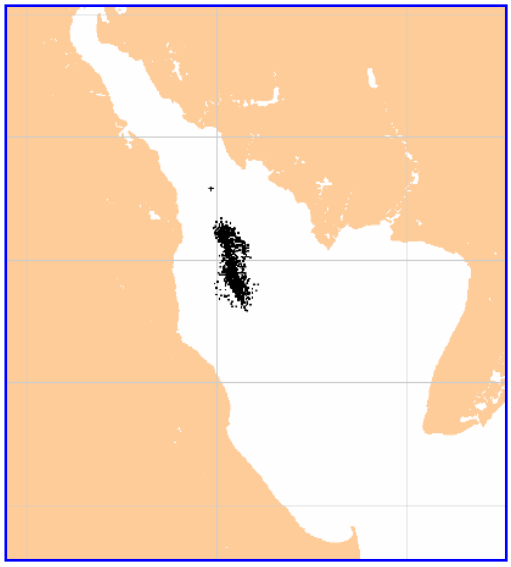
Table 3.4 The Estimated Gallons of Oil and Emulsion on Six Shoreline Segments for the Delaware Bay Scenario if No Response Options are Employed.

Shoreline	Oil	Emulsion
Bombay Hook	8,040	72,000
Egg Island area	420	3,800
North Cape May	64	600
Cape May	6,672	60,000
Cape Henlopen	3,012	27,000
South of Cape Henlopen	3,292	29,600

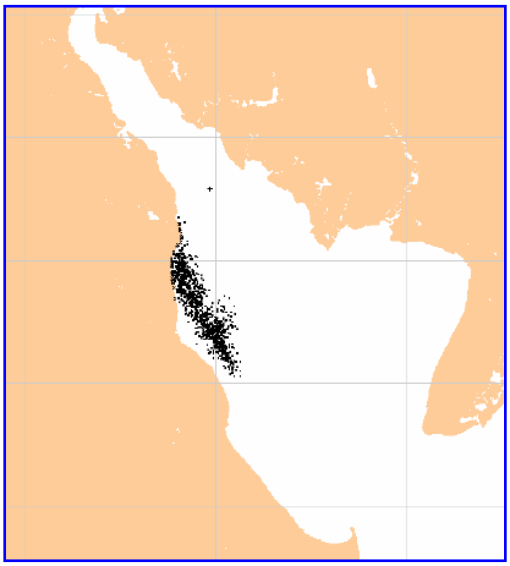
Average concentrations in the water column with no response (Figures 3.4 to 3.7) do not exceed any of the thresholds presented for adult crustaceans or for sensitive life history stages. The maximum concentrations exceed the 'low level of concern' threshold for sensitive life history stages but not for adult crustaceans. This situation would apply only to animals which remained in contact with maximum concentrations for a period of at least several hours. In general, there is insufficient oil dispersed or dissolved to represent a threat to water column organisms except in the immediate vicinity of the slick, and then only in the surface layer (0 to 2 meters).



A: 1 Hour



B: 7 Hours



C: 18 Hours

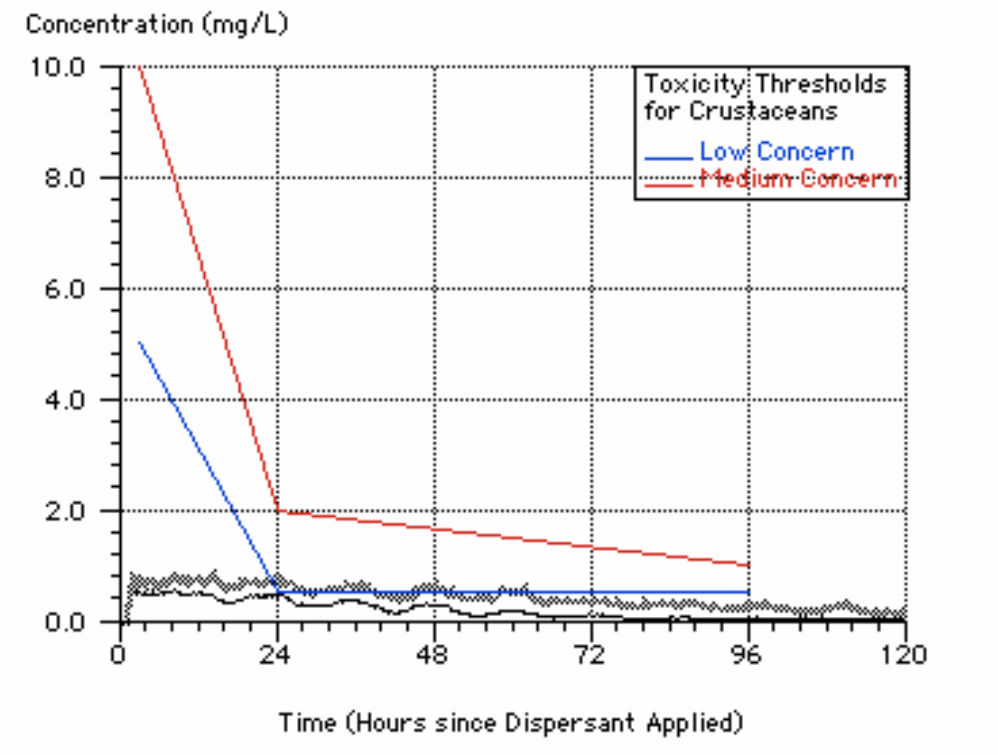

Figure 3.5 *Toxicity thresholds for dispersed oil for adult and juvenile crustaceans compared to maximum and average dispersed oil concentrations at 0 to 2 meters without the use of dispersants (based on the values presented in Table 4.1).*

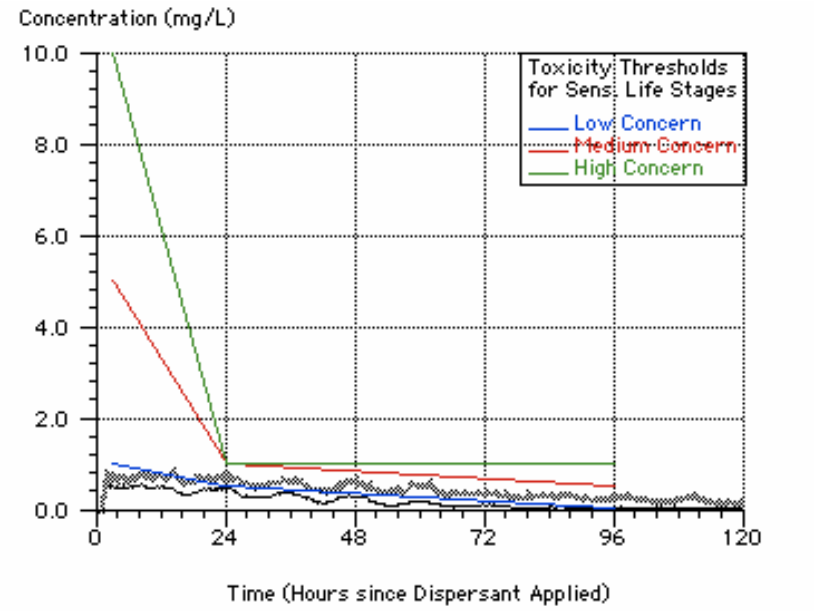

Figure 3.6 *Toxicity thresholds for dispersed oil for sensitive life history stages compared to maximum and average dispersed oil concentrations at 0 to 2 meters without the use of dispersants (based on the values presented in Table 4.1).*

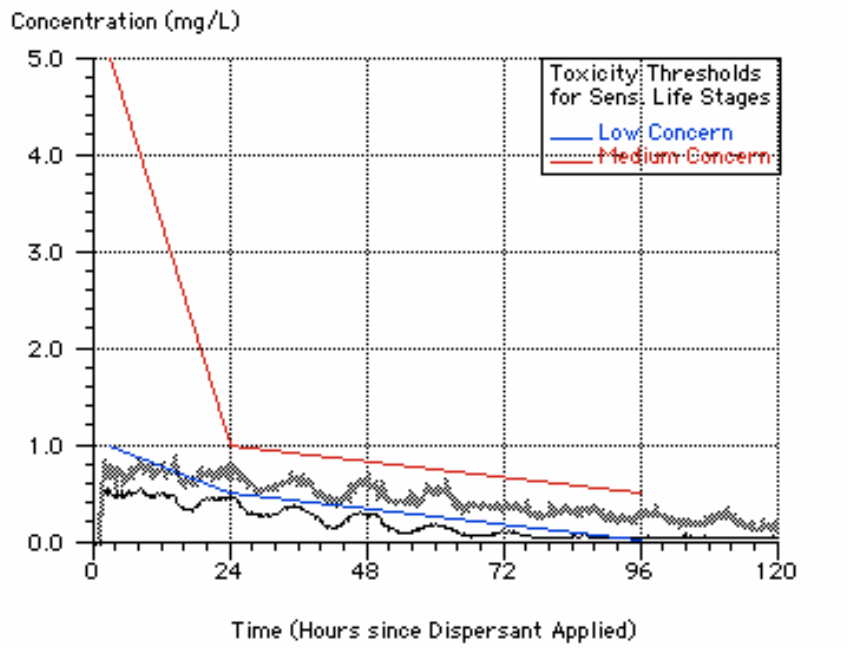

Figure 3.7 *Conservative toxicity thresholds for dispersed oil for sensitive life history stages compared to maximum and average dispersed oil concentrations at 0 to 2 meters without the use of dispersants (based on the values presented in Table 4.1).*

Snapshots from the dispersed oil modeling results are shown in Figure 3.8 for 85% effectiveness and in Figure 3.9 for 35% effectiveness. For clarity, oil remaining on the surface has been removed from the frames. Figure 3.10 depicts fate of the oil slick when dispersants are applied at 85% effectiveness, while Figure 3.11 shows the effect of the dispersant application at 6 hours on emulsion formation.

By comparing Figure 3.3 to Figures 3.8 and 3.9, the differences in the trajectory for the surface oil and the dispersed oil plume are noticeable. This is even more obvious in the QuickTime trajectory movies on the workshop CD. The dispersed oil plume moves with the estuarine currents, and shows a strong tidal oscillation, while the surface slick responds to the wind field. As a result, different areas of the estuary are exposed when dispersants are applied. A second obvious result is the dramatic reduction in emulsion formation, and in the amount of oil stranding (Tables 3.2 and 3.3). For example, after 48 hours almost 79,000 gallons of emulsion have beached with no response, while with dispersant application at 85% effectiveness this number is reduced to approximately 13,500 gallons. On-water mechanical recovery, assuming an effectiveness of 25%, would lead to a reduction similar to that estimated for dispersants at 35% effectiveness, assuming that the emulsion could be effectively recovered and stored in the short term.

This reduction in shoreline impact with dispersant use comes at the expense of increased exposure to organisms in the water column. Figure 3.12 shows the maximum and average water column concentrations in the top 2 meters when dispersants are used at 85% effectiveness. Maximum concentrations initially peak at approximately 2 parts per million (ppm), and rapidly decline over time as dilution occurs. Average concentrations peak slightly later at approximately 0.75 ppm and then also decline with dilution. Table 3.5 shows the area of the dispersed oil plume (defined as any grid cell in the model where the presence of oil is predicted) over time, along with the average and maximum concentrations. For comparative purposes, the approximate volume of the Delaware Bay is 13 billion cubic meters, and the approximate surface area is 1,773 square kilometers (Sutton *et al*., 1996). So the contaminated area at 48 hours amounts to 4.7% percent of the total area of the Bay. The affected volume at that time, based on the assumed mixing depth of 2 meters, is less than 0.1%.

Table 3.5 Estimated Dispersed Oil Plume Extent and Concentrations, Over Time, When Dispersants are Used at 85% Effectiveness.

Hours Into Spill	Area (sq. km.)	Depth (m)	Average Concentration (ppm)	Maximum Concentration (ppm)
0	0.0	0.0	0.00	0.00
6 (Spill Dispersed)	25.7	2.5	1.00	2.00
12	38.8	4.5	0.75	1.60
24	58.3	2.5	0.47	0.63
48	83.6	2.0	0.34	0.66
72	213.5*	2.5	0.09	0.37

* Approximately 50% of the plume is outside of Delaware Bay at this time.

Figure 3.13 compares the maximum and average water column concentration in the top 2 meters when dispersants are used at 85% effectiveness to the thresholds of concern for adult and juvenile crustaceans. Figure 3.14 shows the same information at an expanded scale. Only the low level of concern threshold is exceeded, and then only for the maximum concentrations, which do not represent a large proportion of the plume. Figure 3.15 compares these concentrations to the conservative toxicity thresholds for sensitive life history stages. In this case the low level of concern threshold is exceeded for both the average and maximum concentrations, and the medium and high level of concern thresholds are approached at the 24-hour mark for the maximum concentrations. This suggests a low risk to planktonic organisms present in the dispersed oil plume, with a higher risk to those in the areas of high concentration. Figure 3.16 compares these concentrations to the low level of concern threshold for adult fish. The maximum concentration curve approaches the threshold at 24 to 36 hours, but does not exceed it. Figure 3.17 compares the exposure profile at a specific point in the Bay to the toxicity thresholds for adult and juvenile crustaceans (as representative of the benthic community). The data suggests that benthic organisms would be at low risk during this spill scenario.

Finally, Figure 3.18 shows the maximum and average concentrations of dispersed oil when dispersants are used at 35% effectiveness. Figure 3.19 compares these values to the thresholds for sensitive life history stages. This is the only comparison presented, since it is the only one where predicted values at 35% effectiveness approached the thresholds. In this case, the low level of concern threshold falls between the average and maximum concentration curves, suggesting that animals in the portions of the plume with higher than average concentrations could be at risk.

4.0 The Results of the Risk Analysis Process

Focus groups developed and then used the risk matrix presented in Figure 4.1 (see Section 2.0). Each focus group was tasked with reviewing the scenario, the modeling results, information on exposure and sensitivity to oil and dispersed oil, and basic life histories and distributions in order to develop a group estimate of the percent of each resource affected and the recovery time. In the initial evaluation, the groups used alphanumeric codes to rate the level of concern. After the scaling was developed in plenary session, color coding was used to indicate summary levels of concern.

		RECOVERY			
		> 10 years (SLOW) (1)	**5 to less than 10 years (2)**	**1 to less than 5 years (3)**	**< 1 year (RAPID) (4)**
PERCENT OF RESOURCE AFFECTED	**> 50% (LARGE) (A)**	**1A**	**2A**	**3A**	**4A**
	30 to 50% (B)	**1B**	**2B**	**3B**	**4B**
	10 to 30% (C)	**1C**	**2C**	**3C**	**4C**
	0 to 10% (SMALL) (D)	**1D**	**2D**	**3D**	**4D**

Legend: Red cells represent a "high" level of concern, yellow cells represent a "moderate" level of concern, and green cells represent a "limited" level of concern.

Figure 4.1 *Definition of levels of concern for the Delaware Bay risk assessment.*

Using the ranking matrix requires that the participants develop estimates of the proportion of the resource affected, and how long it will take the resource to recover. A key factor in determining whether or not a resource is affected is to apply thresholds at which impacts, either acute or chronic, would be expected to occur for the various resource groups under consideration. This is perhaps the most difficult part of the consensus process, and has been discussed in detail at all of the workshops. In this case, as in other workshops, very conservative assumptions were presented by the facilitator and accepted as guidelines by the participants.

The only thresholds which can be generally quantified are those related to aquatic toxicity. Table 4.1, reproduced from the Guidebook, presents a series of concentration thresholds which were made available to the participants. These values are based on a summary of published toxicity information initially developed during the early workshops. This table was reviewed by the National Academy of Sciences panel which recently considered issues related to dispersant use, and is included in their report (NRC, 2005).

Impacts to birds, mammals and turtles on the water surface were assumed if there was a high probability of any contact with the surface oil slick. The nature of these impacts was developed during the focus group discussions. For shoreline resources and habitats, damage was assumed if oil contacted the habitat. Table 4.2 presents estimates of shoreline exposure, based on varying loading rates. It was used for general guidance only and is based on average concentrations; actual shoreline accumulations of oil are generally irregularly distributed, especially at low concentrations.

It is important to keep in mind that the participants used the information available to them to develop levels of concern about the risk, and the risk scores do not represent a prediction of actual impacts. Instead they represent a consensus on the part of the participants that such consequences were likely to occur under the scenario under consideration.

Table 4.1 Consensus Exposure Thresholds of Concern (in ppm) for Dispersed Oil in the Water Column.

Continuous Exposure	Level of Concern	Protective of Sensitive Life Stages	More Protective Criteria	Protective of Adult Fish	More Protective Criteria	Adult Crustacea/ Invertebrates	More Protective Criteria
3 hours	Low	<5	<1-5	<10	<10	<5	<5
	Medium	5-10	5-10	10-100	10-100	5-50	5-50

96 hours	Low	<1	<0.5	<1	<0.5	<1	<0.5
	Medium			1-5	.0-5	1-5	.5-1
	High	>1	>0.5	>5	>5	>5	>1

The detailed results for all five focus groups for natural recovery (i.e. no response) are shown in Figure 4.2.[6] There were very high levels of concern in this scenario for organisms on the water surface, salt marshes, mud flats, sandy beaches and sand and gravel beaches in the estuary. There was also concern for sandy beaches (and in one group, terrestrial habitat) on the Delaware outer coast. The concerns within the bay were focused on the risk to shore birds and waterfowl, and to Horseshoe Crabs (adults and particularly eggs on the spawning beaches). The concern on the outer coast was for nesting Piping Plovers (and other threatened and endangered species), which are in the area, but only a few pairs are present. If there was to be any impact to the shore where these birds were known to nest, it was assumed they would be impacted. This elevated the level of concern. There was a consensus that exposure of benthic habitat and water column organisms were not a concern.

[6] For all options except natural recovery protective booming was assumed to be in place and reasonably effective (see Section 2.0 for further discussion).

Table 4.2 Estimates of Shoreline Exposure per Square Meter of Surface.

Width of Oiled Zone	Loading Rate											
	0.1 g/m			1 g/m			10 g/m			100 g/m

1. Oil density = 0.95 gms/cc
2. Soil density = 1.4 gms/cc

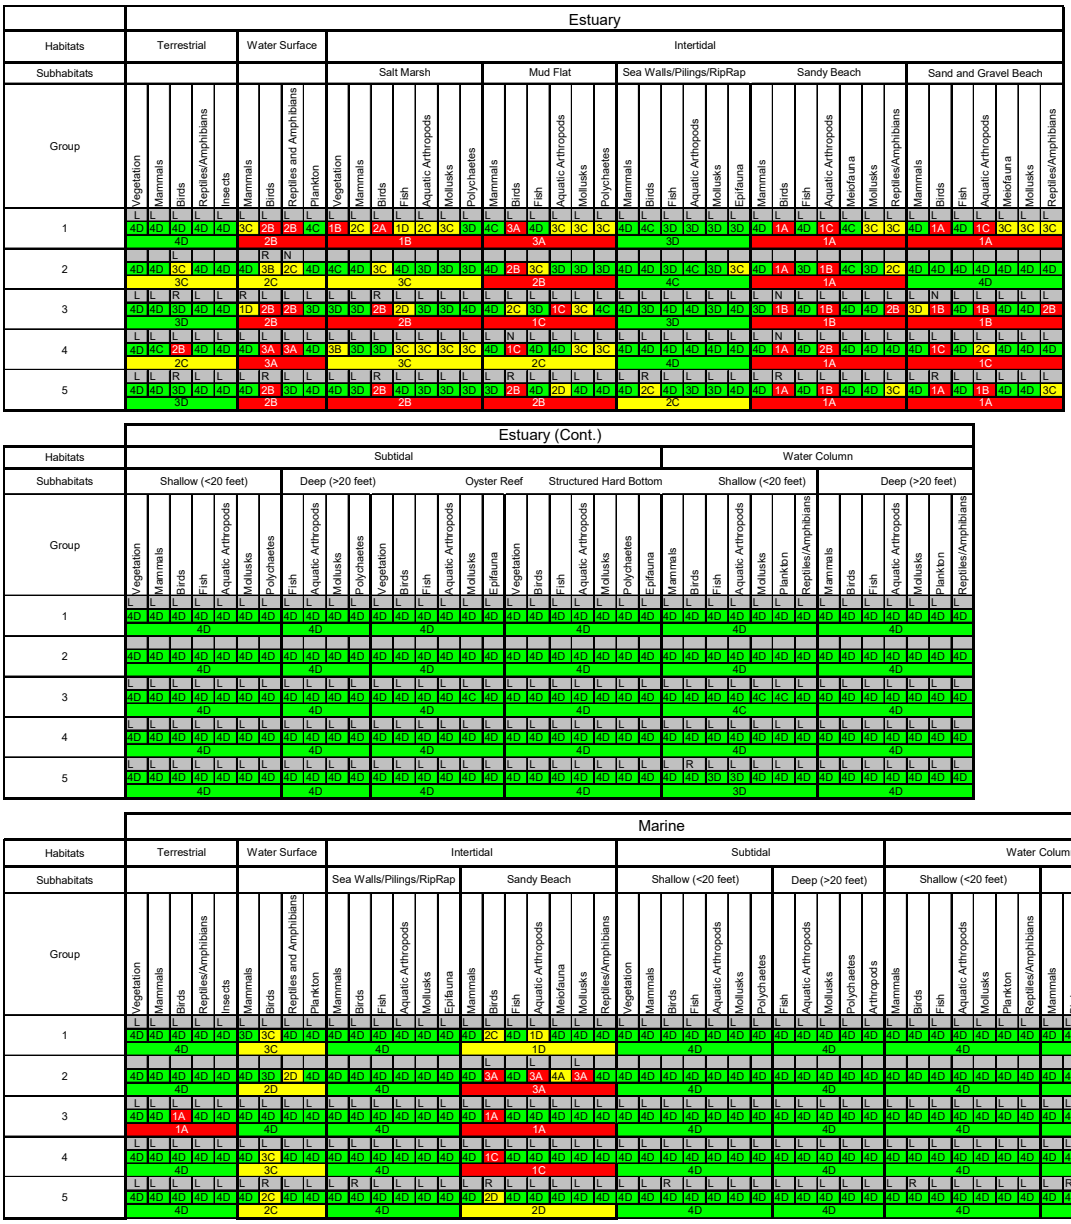
On-water mechanical recovery (Figure 4.3) did not significantly reduce the risk to the habitats of most concern, based on the estimate of the effectiveness of the equipment available (a maximum estimate of 25% recovery was used). Most groups did conclude that effective protective booming would protect salt marshes by preventing oil from entering tidal creeks.

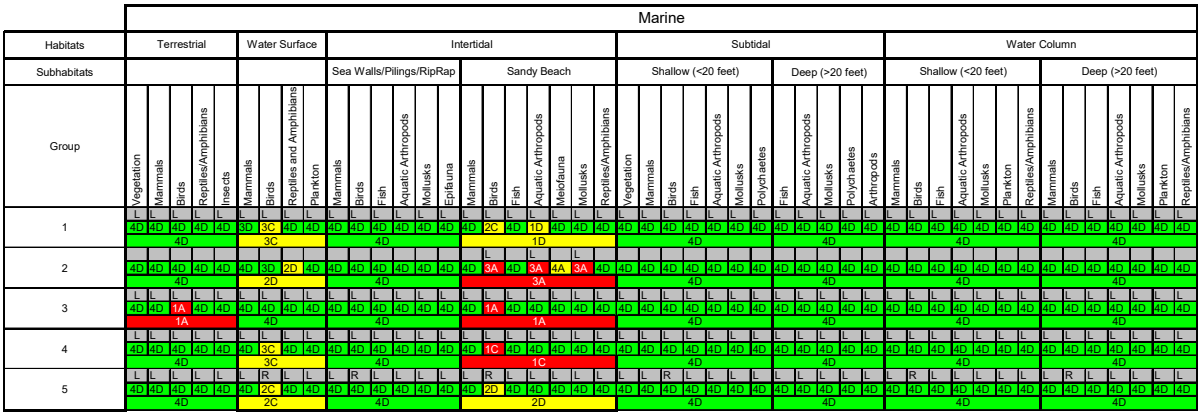
The remaining three response options were analyzed at the second workshop, when only three focus groups were present.[7] The results for dispersant use at 85% and 35% effectiveness are presented in Figures 4.4 and 4.5 respectively. There was a consistent conclusion that the use of dispersants, if highly effective, would significantly decrease the impacts seen for the natural recovery and on-water mechanical recovery options.[8] While there was some increase in the level of concern for water column exposure, none of the focus groups felt it rose to beyond a moderate level of concern. The benefits were not seen by the focus groups unless the application was highly effective, but at the same time the concern for water column exposure also declined.

The final option, on-shore mechanical recovery (Figure 4.5), had essentially the same impacts as natural recovery and on-water mechanical recovery. While all of the groups felt shoreline cleanup was important, they did not believe it would mitigate their primary concerns. In some cases, concern over the impacts of the cleanup itself was expressed.

[7] As discussed in Section 2.0, two of the five groups lost enough members at the second workshop that the remaining participants were assigned to the other three focus groups. The changes in individual focus group assignments are documented in Appendix A.

[8] There was considerable discussion concerning how realistic it was to achieve this level of effectiveness. It was pointed out that the primary objective was to develop a "worst case" risk to the water column for evaluation purposes, and that there was no expectation that this would necessarily be achieved (see Section 2).





Reference Area codes: L = local, R = regional, and N = national or international (see Section 2 for definitions).

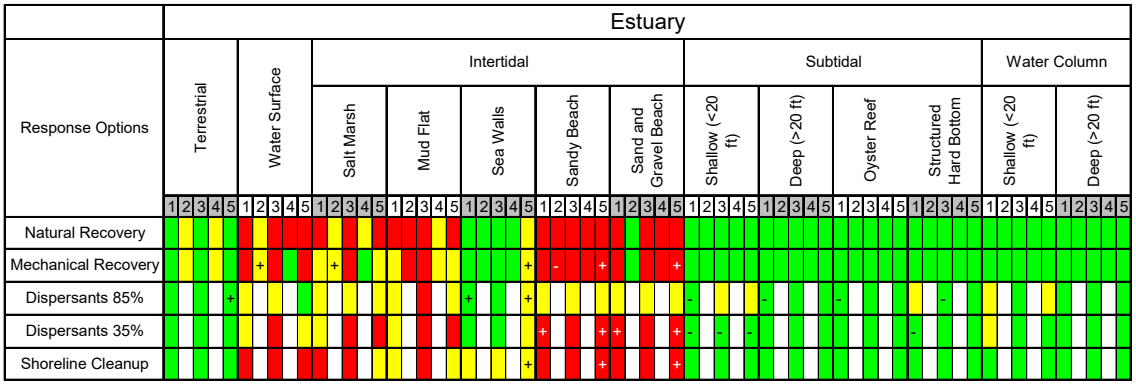
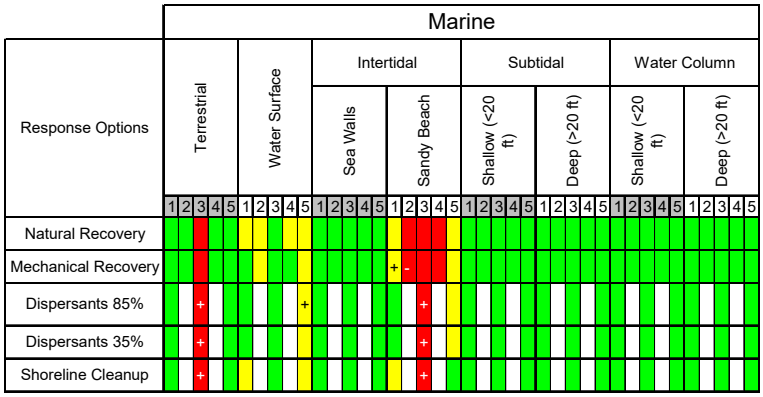
5.0 Summary Risk Analysis Results and Lessons Learned

Table 5.1 presents the summary results for this workshop. Five response options were analyzed along with natural recovery: on-water mechanical recovery, dispersant application at 85% effectiveness, dispersant application at 35% effectiveness and on-shore mechanical recovery. This table is based on the detailed data in Section 4 and allows an easy comparison across response options. All options were analyzed by only three of the five groups, as discussed in Section 2. In summary, participants felt that the most benefit to the environment resulted from the use of dispersants, provided they were relatively highly effective (see footnote 8). The increased risk to the water column was a concern, but was not as high as the risk to the shoreline and water surface areas which would be protected by dispersant use. No attempt was made to resolve differences between focus group scores, but they were discussed. It was emphasized that there is no one best way to respond to a spill, and that the best option is to use all acceptable techniques in concert with one another.





Legend: Red cells represent a "high" level of concern, yellow cells represent a "moderate" level of concern, and green cells represent a "limited" level of concern. There are two group scores per sub-habitat type (columns). A + indicates reduced concern within the broad risk category, while a – indicates an increased concern within the category.

Figure 5.1 *Final relative risk matrix for the Delaware Bay risk assessment.*

5.1 Key Factors Influencing Decisions in this Scenario

On the afternoon of the second day of the second workshop, the focus groups were asked to review the factors which influenced their discussions, and how changes in those factors might alter their conclusions. As future response plans are developed, these issues should be kept in mind. The comments from each of the three focus groups were as follows:

- **Group 1**
  - What if the oil spill volume is larger (10X)?
    - Overall risk is higher.
    - Concern over dispersed oil reaching toxic concentrations in the water column.
  - What if the oil spill is further up river?
    - The available time to respond would be shorter because of closer shorelines.
    - There would be fresh water vs. brackish water issues (because of dispersant use limitations in fresher water).
  - What if it is a different season?
    - Summer - Recreational uses are both a concern for protection and for interfering with response. Impact of higher temperatures on evaporation of the oil.
    - Fall - Driver would be migratory birds and waterfowl, as well as butterflies.
    - Winter - Response logistics due to the season (e.g.- frozen water, access, etc.).
    - Overall for all seasons - Living resources are drivers. Need for awareness of sensitive organisms with information from environmental managers on wildlife and vegetation (e.g., oysters and fisheries).
  - What if a different product was spilled?
    - Need a list of bulk petroleum materials entering the port and a table of effective dispersability of those products.
    - How effective should a dispersant be to be used?
    - Does the petroleum product shipped in the estuary vary by season?
  - General comment
    - Diagram that reflects the dispersant use policy areas in the Area Contingency Plan should be more detailed with bathymetry of the estuary.

- **Group 3**
  - Drivers - For most recovery methods, birds/Horseshoe Crabs/mollusks were species of concern (Piping Plover, eagles, etc.). Diamondback Terrapins were also important to this group.
  - Theory behind scores
    - Time of spill was critical to species that drove scores.

        - Spatial spread of oil was a factor – large portion of marshes and mudflats in entire bay (impact to individual marsh may be large, but to the entire resource, the impact would be less).
        - Delaware side is more heavily impacted during initial hours of spill.
        - Group did not feel 25% mechanical recovery affected scores enough to create improvement.
        - Dispersants were beneficial at 85%, but not so much at 35% effectiveness.
        - Food web dynamics become more important in dispersant response scenario, as do juvenile/larval stages in various species.
        - During on-shore mechanical recovery, there were not many changes in scores due to tradeoffs (less oil, but greater impact due to staging and equipment).
    - Change in volume
        - Greater impacts overall, longer mechanical and on-shore recovery time.
        - Resource levels may change, for example, local to regional.
    - Change in season
        - Species of concern would shift (e.g., fish spawning, mussel spat, dolphins, etc.).
        - Important to note that there is no time where there is not a species of concern, either in water or on-shore.
        - Decision related to dispersants may change given time and specific resource.

- **Group 5**
    - What were the drivers affecting decisions in this scenario?
        - Concern for birds (Red Knots, Piping Plovers) at the water surface, mudflats, and beaches.
        - Horseshoe Crabs on beaches and mudflats.
        - Minimal effects in water column and benthos.
        - Economic and political drivers were not considered.
        - When dispersants were assumed to be effective (85%), shoreline impacts were significantly reduced to a point where they outweighed concerns for the water column effects.
        - Assumed that logistics for getting dispersants was not an issue.
    - Modifications
        - Change Season to July/August - Much larger concern for fish, oyster, crab, clam larvae would affect decision to use dispersant. Lower concern for birds and horseshoe crabs would affect response decisions.
        - Change in Location (up river in May) - Spawning of Striped Bass, Shad, etc. in upper river sections would affect decision to use dispersants. Lower concern for birds.
        - Change in Location to Offshore Ocean (1/2 mile) - More likely to approve dispersant use due to concern for oiling beaches and lower concern for dispersed oil in water column.

- Increase Size of Spill 10x - Increased concern for all species on beaches, marshes, mudflats for natural recovery. Questionable whether dispersants will be worth using on majority of slick. May want to selectively use dispersants to protect selected areas.

5.2 Consensus Recommendations

On the last day of the workshop, the participants reviewed the comments listed in Section 5.1, and developed the following list of consensus comments for consideration in future oil spill response planning efforts. They suggested these be presented to the Sector Delaware Bay Area Committee for consideration.

- This scenario focused on impacts to the mid and lower bay and did not consider treatment options for cleaning upper bay and river. The Area Committee should pursue future workshops to address these areas.
- Update the Environmental Sensitivity Index (ESI) maps (a lot of work, relating to ecologically significant resources, has been done in the past 10-15 years that is not reflected in those maps):
    - Database is somewhat rigid, and sometimes difficult to use, since it doesn't prioritize the resources,
    - We do not have the most up to date information related to ecologically significant species and critical habitats in the atlas (e.g., oyster, Atlantic sturgeon, white cedar swamps, freshwater tidal wetlands),
    - Consider breaking out eggs, larvae and juveniles rather than having the information combined,
    - Consider using C. Stern information system, United States Fish and Wildlife Service, to capture this information,
    - Involve non-governmental organizations during ESI data collection.
- Initiatives to integrate ESI maps with Geographic Information System (GIS) systems are worthwhile. This could facilitate rapid decisions between the Incident Command System and resource managers.
- The Area Committee needs to address ways to improve GIS information exchange/centralization.
- USCG would benefit from obtaining internal GIS capabilities to enhance inter-agency planning and response.
- Need more information to assess the impacts of oil and dispersed oil on:
    - eggs/juvenile/adult Horseshoe Crabs,
    - post D-hinge stage larval oysters and mussels (e.g., veliger, etc.),
    - indirect food web impacts on critical species.
- Evaluate Coastal Response Research Center research and other funding opportunities to address these needs.
- Need to better integrate information needs with response options (provide localized information on ESI maps; focus research needs with response options).
- Suggest developing a working committee to identify scenarios throughout the area of responsibility (conditions and locations) where dispersants would NOT be used,

would be IDEAL to use, and where the "grey area" in between occurs (natural resource trigger points):
    - Although this was a beneficial exercise, it did not provide enough detailed information to assess whether dispersant use would be a viable response under other conditions or scenarios,
    - Confidence in the benefit of using dispersants would improve if more detailed information was provided on the extent of shoreline oiling for a given scenario.
- Take advantage of spills of opportunity to explore fate and effects.
- Need to develop a method to rapidly determine how effective a dispersant application will be on an actual spill.
- Evaluate current process to assess "real-time" dispersant use to streamline the decision-making.
- Residence time and operational limitations are key components of dispersant use decision-making.
- Protective booming strategy is an effective mechanism in the ACP, so the Area Committee should re-evaluate it for further improvements (e.g., resource protection and prioritization).
- The Area Committee should evaluate shoreline protection strategies for ecologically important areas (e.g., Horseshoe Crab beaches, Red Knots).
- The identification of oil collection areas could be an important component of shoreline protection.
- Develop " protection and response" strategies for Atlantic Ocean coastal bays and beaches.
- Closer linkage of GNOME model (NOAA) output with local hydrographic predictive modeling to enhance evaluation of response options.
- The Area Committee should engage resource managers, NGOs, and local resource experts in planning, exercises and/or training opportunities.
- Communication is an important part of oil spill response management. The Area Committee should continue to evaluate portals/partnering for rapid information dissemination.
- Area Committee meetings are open to the public. ERA workshop participants are encouraged to attend.

July 21, 2015

Dear ERA Workshop Participant:

I would like to extend my sincere thanks to all those who participated in this Ecological Risk Assessment (ERA) for Sector Delaware Bay. This ERA focused on assessing the risks from specific crude oils moving through the Sector's Area of Responsibility and planning for the best way to respond to an incident involving Bakken crude oil and diluted bitumen.

Historically, one million barrels per day (BPD) of crude oil are transported through this region. Due to the energy renaissance, three different Class I rail companies now transport 588,000 BPD Bakken and 103,000 BPD diluted bitumen to five nearby refineries. This increased risk must be accompanied by proper contingency planning and updated response strategies. To maintain an effective and safe response posture throughout the eastern corridor, as the Federal On-Scene Coordinator and Co-Chair to the Area Committee, I feel this ERA is both timely and pertinent, not only in Pennsylvania, New Jersey, and Delaware, but nationwide.

We need to understand the properties and behavior of these oil products while defining appropriate response options to mitigate their associated potential risks. The ERA represents the collaborative efforts of subject matter experts and stakeholders from numerous disciplines working together to accomplish these goals, and I deeply appreciate their participation in this significant undertaking.

Sincerely,

B. A. Cooper
Captain, U.S. Coast Guard
Federal On-Scene Coordinator
Commander, Sector Delaware Bay

Preface

The original report was provided to US Coast Guard Sector Delaware Bay in September 2015. The authors received thoughtful insight from two external and independent readers. Subsequently, the authors added clarification to address the readers' comments about the use of firefighting foam and the weathering behavior of dilbit oil.

January 2016.

Acknowledgements

Scientific and Environmental Associates, Inc. (doing business as SEA Consulting Group – SEA) wishes to acknowledge first and foremost the willing and constructive technical collaboration among all those who were involved in this project, which directly contributed to the new, substantial work performed in this ERA. We thank the project sponsor representatives from Sector Delaware Bay for their considerable assistance: LCDR Michael Weaver, LT Eric Nielsen, and Mr. Gerald Conrad, as well as LCDR Tracy Wirth, who initiated this project. SEA and the sponsors of this project extend their sincere appreciation to all the participants in the risk assessment workshops.

We also want to recognize the contributions of the Project Committee, some of whom served as subcommittee and workgroup leads: Mr. Clay Stern (U.S. Fish and Wildlife Service (USFWS)), Mr. Ed Levine and Mr. Frank Csulak (National Oceanic Atmospheric Administration (NOAA)) Scientific Support Coordinators), Mr. Mike Towle (U.S. Environmental Protection Agency (EPA) Region III), Mr. Rich Gaudiosi (Delaware Bay and River Cooperative (DBRC)), Mr. Bennett Anderson (Delaware Dept. of Natural Resources and Environmental Conservation (DNREC)), Mr. Robert Bauer (Pennsylvania Dept. of Environmental Protection (PADEP)), Mr. Patrick Digangi (NJ Depart. of Environmental Protection (NJDEP)), and to the NOAA Emergency Response Division for developing scenario-specific oil behavior and fate modeling and the resources at risk report from these oils.

Special recognition is extended to Mr. Stern for his substantial technical contributions regarding Section 7 consultations, the resource classification, the update of the risk ranking matrix, and his thoughtful suggestions throughout the project. Further, special recognition is also extended to Dr. Kelly Scribner of the Center for Toxicology and Environmental Health, LLC (CTEH) for her valuable assistance on human health and safety aspects of Bakken and dilbit crude oils and sharing her direct experience in responding to rail incidents, in addition to developing the initial human safety and health conceptual model.

We acknowledge with appreciation the generous logistical support by the members of the Delaware Bay and River Cooperative for the workshops. We greatly appreciate the efforts of the workshop recorders, Rebecca Weissman and Stacey Burger from SRA and Melinda McPeek of SEA, for capturing the discussions in the plenary sessions and the scenario workgroups.

Finally, we would like to acknowledge the special presentations and briefings (in order given) at the workshops by:

- Mike Towle, EPA "Bakken Crude Oil February 2015 Testing at OHMSETT"
- Dr. Kelly Scribner, CTEH "Health and safety concerns associated with response to crude oil releases"
- Chief Jim Kelly, Sunoco Logistics – Discussion on Foam, Logistics and Port Asset for Fire & Spill Response
- Suzanne Lemieux, API – Industry safety course for moving crude by rail
- Dr. Michel Boufadel, New Jersey Institute of Technology - Bakken and Dilbit Oil Fate
- Bryan Naranjo, Norfolk Southern Railroad - Norfolk Sothern's Crude Oil by Rail Planning, Training and Response

- Mike Austin, CSX - CSX's Crude Oil by Rail Planning, Training and Response

Contractor support to assist in the planning and facilitation of the workshops and in the preparation of the report was provided by CAPT Joseph Loring, Chief of the CG-Office of Marine Environmental Response (MER) Policy, Headquarters, USCG (G-RPP) under Task Order HSCG23-13-F-MPP059, issued under Contract Number (HSCG23-11-A-MPP439) to SRA International. The support and guidance of the MER Project Manager, Jonathan Smith, also is gratefully acknowledged.

Executive Summary

In 2015, the United States Coast Guard (USCG) Sector Delaware Bay sponsored the project, "Consensus Ecological Risk Assessment of Potential Transportation-related Bakken and Dilbit Crude Oil Spills in the Delaware Bay Area: Comparative Evaluation of Response Actions". The aim of the Sector Commander, who is the designated Federal On-scene Coordinator (FOSC), and the Area Committee was to update the Area Contingency Plan (ACP) and improve preparedness to oil spills in the Sector's area of responsibility (AOR) by identifying timely and effective response actions that can enable resource protection and recovery in the event of future spills from Bakken and diluted bitumen (dilbit) oils. Project-specific objectives were to assess the risks from these two crude oils, which are moving through the Sector's AOR and plan for the best way to respond to incidents involving these oils since they are transported via rail, barge, and tanker throughout the AOR. Funded by USCG headquarters (HQ), a related project objective was to consider specifically threatened and endangered (T/E) species in accordance with USCG HQ guidance on Section 7 consultations (Gelzer, 2013) pursuant to the Endangered Species Act (ESA) and Essential Fish Habitat (EFH) under the Magnuson-Stevens Fisheries Conservation and Management Act (MSA).

This project adapted the consensus ecological risk assessment (CERA) process, as described in *Developing Consensus Ecological Risk Assessments: Environmental Protection in Oil Spill Response Planning. A Guidebook* (Aurand et al., 2000), to satisfy this project's objectives. Previous CERAs assessed the risks associated with a single oil type in one or two scenarios, the variables being different spill volumes or, in some previous ERAs, spill location. This CERA assessed two types of crude oil with different properties and behavior, in five spill scenarios involving rail, barge, and tanker modes of transportation, in two seasons (winter and spring), and in three different settings, i.e., creek (freshwater), river (brackish/salt water depending upon the volume of fresh water flowing into the river), and bay (saltwater). Special consideration was given to T/E species throughout the process. The properties of these oils (Bakken-highly flammable and dilbit-weathering and sinking) necessitated developing a new set of response actions, and evaluating the risks of the spilled oil and response actions in two phases, i.e., initial emergency phase (initial 4-6 hours) and longer-term (6 hours onward, especially 4 – 7 days). A new set of 10 response actions and new conceptual models were developed and the risk ranking matrix was revised. Due to the serious fires in recent incidents involving Bakken oil, the project assessed human health and safety risks in addition to ecological risks.

To accomplish the full project scope, a Project Committee comprising members of the Area Committee and resource trustee agencies worked with the USCG and consultant staff assigned to this project to: guide project activities; lead subcommittees; lead scenario workgroups in the two workshops; and provide guidance about this report's organization, including key points to highlight. Past CERA workshops involved 30-50 participants in two 3-day workshops, separated by about a month. This CERA involved nearly 90 participants in two 2-day workshops separated by less than 2 weeks in June 2015. Not all participants attended both workshops, but there was a core majority who participated in both.

Due to the broad project scope and unlike previous ERA's where at least two workgroups separately evaluated the same scenarios and then developed a final consensus among all participants, the workgroups in this project assessed separate scenarios and achieved scenario-

specific consensus, rather than a consensus across all workgroups about all scenarios. That said, some general findings about response actions to spills of Bakken and dilbit oil include:

- Assuming health and safety measures of first responders (e.g., fire fighters and pollution responders) are successful, risks to human health and safety and social-economic resources from a fire as well as fire-fighting foam were scored as a moderate level of concerns.
- The ecological risks associated with the use of fire-fighting foam in fresh, brackish or marine waters were scored with a moderate concern.
- Participants assigned higher levels of concern to the ecological risks associated with a spill of dilbit oil, compared to a spill of Bakken crude oil.
- For transportation-related spills of Bakken oil, in general, the workshop participants found that the "No response other than monitoring" option was considered of limited or moderate level of concern when deemed appropriate for the scenario conditions, both at the 4- to 6-hour response frame or at the 4- to 7-day post discharge. In most cases, the participants found that there was very little change in concern levels when considering the various response action versus the "no response" action. Although some of the levels of concern did increase from low to moderate (green to yellow), this increase in concern did not require a change in response options. The highest level of concern in Scenario 1 (rail, Philadelphia, Schuylkill River, freshwater) was with the use of extinguishing agents or for vapor suppression in the intertidal zone for both the initial response and over the 4- to 7-day response times.
- For transportation-related spills of dilbit oil, in general, the workshop participants found that the "No response other than monitoring" option provided a moderate to high level of concern, both at the 4- to 6-hour response timeframe to the 4- to 7-day post discharge. In most cases, the participants found that there was very little change in concern levels when considering the various response action versus the "no response" action. Some of the levels of concern did increase for response actions over the 4- to 6-hour timeframe to the 4- to 7-day period from low to moderate (green to yellow). The high level of concerns (red) were scored in Scenario 5 (barge, Delaware River, brackish water) regarding the use of most response options deemed applicable for use in the intertidal, mid-water, and benthic zones for both the initial response and over the 4- to 7-day response times. Similar concerns were also expressed for Scenario 4 (rail, Mantua Creek, freshwater) when considering the risk of shoreline clean up and oil detection / mapping methods for the intertidal and midwater zones.
- For dilbit oil spills, participants recommended that rapid containment and removal of the oil from the water surface is the highest environmental priority during the initial few hours of response, to limit spreading of the oil and reduce potential extent of contamination on both shoreline and benthic habitats. If the oil is not recovered early on, especially in freshwater, the oil will likely begin to pick up sediments and submerge, making it very difficult to detect and recover without doing additional damage to the environment.
- The presence of T/E animals and plants and some other organisms, such as diamondback terrapin (turtle) and freshwater mussels, are drivers that increase the level

of concern in these scenarios from both the oil and response actions which could impact them, e.g., trampling from shoreline cleanup and oil removal using mechanical means in nesting season.

- A response action scored with a high level of concern (red) is a prompt to further review and assure that response actions would not adversely affect the species of concern; it is not intended to prevent or stop response actions. This ranking represents a need for follow-up action by the Area Committee and Regional Response Team (RRT) to more fully address whether certain response actions will be allowed and, if so, under what circumstances, e.g., in certain seasons or under specific conditions.

This page intentionally left blank.

1.0 Introduction

In 1998, the USCG began sponsoring efforts to develop comparative methods that would enable the evaluation of relative risks associated with three primary categories of marine/coastal oil spill response actions – mechanical recovery, dispersants, and *in-situ* burning. The results of the risk assessment would be used to inform pre-spill planning decisions that are reflected in ACPs and consistent with policies in the Regional Contingency Plans around the United States. Interest in selecting response options based on a risk/benefit analysis predates the 1998 initiatives, but efforts since the 1998 project are different in that they emphasize a consensus-building approach to evaluate potential risks and benefits. USCG Headquarters (formerly G-MOR, now MER) sponsored the development of a guidebook on this process. That document, entitled *Developing Consensus Ecological Risk Assessments: Environmental Protection in Oil Spill Response Planning. A Guidebook*, is available from MER (Aurand *et al.*, 2000). A previous CERA, which followed that guidance, was conducted for the Delaware Bay in 2006 for the above-mentioned response options. The focus of this CERA addresses a new set of response actions to spills involving two specific types of crude oils, i.e., Bakken and diluted bitumen (dilbit), which have become part of the USCG's evolving responsibilities in the recent national energy renaissance.

The CERA process is designed to help oil spill decision makers to compare ecological consequences of specific response options, especially in nearshore or estuarine situations. This is important because when an incident occurs, rapid decisions must be made to implement the optimal actions intended to mitigate environmental risks from the oil and response actions, as well as ensure public safety and the safe passage of commerce. Given multiple regulatory authorities and response options, it is most practical to consider and reach agreement among those with inter-jurisdictional responsibility about the potential limitations and benefits of available risk mitigation options before time-critical decisions have to be made during response. Due to the length of time involved to conduct the entire process (i.e., a total of several months), conducting an incident-specific ERA is impractical for the emergency phase of an actual spill of waterborne oil. Notwithstanding, knowledge gained by participants in the CERA process facilitates real-time decision-making by enabling a review of significant risk factors in relation to previously considered response options; some of which may still be generally applicable and/or could be modified to implement during an actual incident.

The CERA process allows decision makers to evaluate effects to ecological resources through cross-response comparisons. In this structured, ***qualitative***, and analytical approach, participants develop a shared understanding and basis for evaluating impacts. Moreover, through this process, participants develop technically-feasible rationale to support their consensus findings that can be used to develop appropriate response strategies to include in the ACP.

The CERA process uses a series of matrices and other tools to structure discussions and capture group consensus about risk management options (i.e., response options), stressors, resources at risk, and the impact of stressors on identified resources. The oil spill CERA process typically involves 2-3 months of planning followed by two 2- or 3-day facilitator-led workshops. The ideal size is around 20-30 participants for two scenarios, including spill response managers, natural resource managers and trustees, subject matter experts, and non-governmental organizations. The goal is to achieve consensus interpretations of potential risks and benefits associated with selected response options based on scenarios developed by local participants.

Time between the two workshops, usually at least a month, is used by participants to research issues of concern before developing final conclusions. The process focuses heavily on achieving a consensus interpretation of available data and technical information. Therefore, it is important to have broad representation in the assessment process to build joint support for and credibility in the findings.

The CERA process includes three primary phases - ***problem formulation, analysis,*** *and* ***risk characterization,*** plus a fourth post-workshop phase of ***documenting and applying results***. Details of the process are described in the USCG *Guidebook* (Aurand *et al.*, 2000). In the first phase, problem formulation, participants develop a scenario for analysis, identify resources of concern along with associated assessment thresholds, and prepare a conceptual model to guide subsequent analysis. In the analysis phase, participants characterize exposure and ecological effects. The risk characterization phase, directs the assessment, using standard templates and simple analytical tools that define and summarize the assessment for the resources of concern against each evaluated response option. Finally, participants complete a risk characterization. During this phase, participants interpret their results in terms of the advantages and disadvantages of each response option in comparison to the impacts of leaving the oil in place to naturally attenuate with monitoring (NAM). The risks of impacts from oil alone are compared to the risk of each category of response action on various resources at risk from the spill.

This CERA adapted the 2000 Guidebook, as discussed in Section 3.0, to assess the spill response risks associated with new transportation-related scenarios involving oils produced in North America, i.e., Bakken and dilbit crude oils.

1.1 Objectives

This project was sponsored by USCG Sector Delaware Bay and the Sector Delaware Bay Area Committee. The project's overall goal is to update the ACP and improve preparedness to oil spills in the USCG's AOR by identifying timely and effective response actions that can enable resource protection and recovery in the event of future spills from Bakken and dilbit oils. Through the CERA process, the sponsors intend to facilitate a better understanding of natural resource trustee and response agency concerns and the concerns of non-governmental organizations (NGOs) that have particular interests in the Delaware River and Bay ecosystem.

Project-specific objectives are to assess the risks from two crude oils (Bakken and dilbit) moving through the Sector's AOR and plan for the best way to respond to incidents involving these oils as they are transported via rail, barge, and tanker throughout the AOR. The aim of the Sector Commander, who is the designated FOSC, and the Area Committee is to enhance preparedness and understanding of the properties and behaviors of these oil products and mitigate potential risks. Another project objective is to improve the understanding of the sequence and coordination of response actions implemented by first responders, particularly local fire fighters, with the response actions described in the ACP.

1.2 Participants

This CERA was carried out by a Project Committee and workshop participants. Appendix A contains the list of project participants. The Project Committee was comprised of consultant support and members of the Sector Delaware Bay Area Committee, notably representatives from the USCG, EPA, NOAA, USFWS, DNREC, PADEP, NJDEP, and DBRC. Consultant support was provided by SEA Consulting Group and SRA International, Inc.

A total of 172 individuals from 82 organizations were invited. Seventy-eight attended the first workshop; fewer participants attended the second session. Many but not all participants attended both workshops, some attended one session or the other. Participant affiliations also are included in Appendix A. At the first workshop (June 9-10, 2015), participants were divided into five breakout groups, one for each scenario. These were also their assignments in the second workshop (June 23-24, 2015). Participants who were unable to attend the first meeting were placed in one of the five workgroups during the second workshop.

1.3 Organization of the Report

This report is the project deliverable. It is PDF-1 formatted to be printed as an independent, double-sided report. The report is available electronically from USCG Headquarters MER and USCG Sector Delaware Bay.

Sections 1 and 2 provide an overall ***Introduction*** to the project, and ***Background*** about the ERA process as applied in this project, respectively. The report summarizes the ***Methods*** used to prepare for the assessment activities conducted during two workshops in June 2015 (Section 3); presents the ***Results*** of the assessment (Section 4); and describes the ***Discussion*** among participants who assessed the risks associated with the five scenarios during the workshops (Section 5). In addition, the ***Appendices*** contain relevant, detailed information about this CERA and workshops. Participants used the best available information at the time the CERA was conducted.

Electronic copies of some of the presentations made at the workshops by the sponsors or by subject matter experts and the recorders' notes from the workshops have been delivered to Mr. Gerald Conrad, Contingency Planning Specialist at Sector Delaware Bay. These files are mentioned when appropriate in the text of this report.

2.0 Background

The process is based on EPA's ERA Guidelines (EPA, 1998). It is designed as a planning tool to enable detailed assessment of options for responding to oil spills by a diverse group of participants.

The CERA's goal was to assess the potential benefits and limitations of response actions in relation to the effect of spilled oil alone as a way to make informed decisions about the many response actions that will result in an outcome that is better than not using them, or leaving the oil to attenuate naturally. In that context, this CERA represents a NEBA, which is an approach frequently referred to by U.S. oil spill responders, and by industry globally, for evaluating the potential benefits and limitations of, and tradeoffs associated with, different oil spill response actions.

The planning phase for a NEBA includes: setting the goals of assessment; selecting a limited and feasible suite of alternative actions; defining the temporal and spatial scope of assessment; identifying contaminant and remediation stressors; selecting environmental services and other ecological properties of interest; selecting metrics and methodologies for the comparison of alternatives; selecting a reference state; establishing plausible links between stressors and services (conceptual model); and developing an analysis plan (Fig. 1). As such, the NEBA planning phase is consistent with EPA ERAs.

2.1 EPA ERA Process

The ERA process used by EPA for Superfund[1] (EPA 1998) was the basis for the CERA process for oil spill response. The process was developed to provide a methodical means for risk managers to identify appropriate ways for reducing ecological risks though various cleanup and other mitigation options. An ERA is one tool in the overall management of ecological risks.

In situations where a complex of ecosystem values (e.g., watershed resources) is at risk from multiple stressors[2], a group of risk managers may function as a risk management team. In the EPA process, the ERA is carried out by a risk management team comprising risk managers, risk assessors, and interested parties, such as stakeholders. Risk management teams may include decision officials from federal, state, local, and tribal governments; commercial, industrial, and private organizations; leaders of non-governmental advocacy groups; and other sectors of the public such as property owners.

Risk managers, charged with protecting human health and the environment, help assure that risk assessments provide information relevant to their decisions by describing why the risk assessment is needed, what decisions it will influence, and what they want to receive from the risk assessor. Risk managers are individuals and organizations who have the responsibility, or have the authority to take action or require action, to mitigate an identified risk, such as the members of Unified Command. Risk managers also may include a diverse group of other parties

[1] **Superfund** is the name given to the environmental program established to address abandoned hazardous waste sites. It is also the name of the fund established by the Comprehensive Environmental Response, Compensation and Liability Act of 1980 (CERCLA), as amended.

[2] As defined in the EPA risk assessment glossary, a stressor is any physical, chemical, or biological entity that can induce an adverse response. Stressors may adversely affect specific natural resources or entire ecosystems, including plants and animals, as well as people in the environment with which they interact. http://www.epa.gov/risk/glossary.htm

who also have the ability to take action to reduce or mitigate risk, such as the Natural Resource Trustees (EPA, 1998).

Risk assessors evaluate and characterize exposure to stressors and the relationship between stressor levels and ecological effects, and ensure that scientific information is used effectively to address ecological and management concerns. Stressors from spilled oil may include physical smothering or chemical toxicity of the oil, as well as stressors from actual response actions, such as physical trauma associated with mechanical means to remove oil from the environment. Risk assessors describe what they can provide to the risk manager(s), where problems may occur, and where analytical uncertainty resides.

The CERA process is implemented through consensus among and between risk managers, risk assessors, and other interested and/or affected stakeholders during a multiday interactive workshop. Project Committee representatives, serving in both risk manager and risk assessor roles, helped guide and apply the ERA process. This group also helped ensure that all key participants were appropriately involved. The interface among them from initial planning through to the communication of risk at the end of the risk assessment was critical to ensure that the results of the assessment can be used to support risk management decisions.

During planning, the Project Committee came to agreement on the framework for this risk assessment and available resources needed to achieve the goals. They used information on the area's ecosystems, regulatory requirements, and publicly-perceived environmental values to interpret the goals for use in the ERA. The Project Committee reached agreements about (1) clearly established and articulated management goals, (2) characterization of decisions to be made within the context of the management goals, and (3) agreement on the scope, complexity, and focus of the risk assessment, including the expected output. In this risk assessment, stakeholders and other interested parties also provided an active role in the assessment process by participating in the two workshops, the activities of which are discussed in Sections 3, 4, and 5 of this report.

Many of the previous CERAs that were conducted using the Guidebook (Aurand *et al.*, 2000) were reviewed as background for this project.

2.2 Consultation Process

In accordance with USCG HQ guidance on Section 7 consultations (Gelzer, 2013) pursuant to ESA[3] Section 7(a)(1)[4] and EFH under MSA[5], this risk assessment project served as a collaborative pre-spill planning activity among the USCG, USFWS, the state resource trustee agencies, and NOAA/National Marine Fisheries Service with the intent to develop Best Management Practices (BMPs) strategies that would mitigate, minimize, or have no adverse effect on federally-listed T/E species and their habitats that may be present in any of the ERA's scenarios.

Additionally, this CERA considered the USCG's role pursuant to the National Historic Preservation Act of 1996 (NHPA) Section 106 consultation for cultural resources (as defined), for Area and Regional Planning under the 1997 Programmatic Agreement that directs federal

[3] 16 U.S.C. 1531-1544, 87 Stat. 884
[4] http://www.fws.gov/endangered/laws-policies/section-7.html
[5] http://www.habitat.noaa.gov/aboutus/statutoryauthorities.html

agencies to comply with Section 106 for emergency response actions under the NCP. However, tribal consultations as required on Executive Order 13175 and the Native American Graves Protection and Repatriation Act (NAGPRA) were not addressed during this risk assessment. Instead, this need should be brought forward in the future to the area and regional planning bodies in Regions 2 and 3.

This ERA assesses preliminarily the potential for adverse effects should BMPs identified for ESA, EFH, or NHPA be implemented. In the judgment of the Project Committee, this CERA meets the intent of Section 7.a.1 of ESA. Categories for these T/E species were developed early in the process and incorporated into the evaluation of resources at risk.

3.0 Methods

The Project Committee adopted the methods used in previous CERAs for oil spill response planning (Aurand, *et al.*, 2000; Pond, *et al.*, 2000) which consisted of 12 activities that were conducted over four phases. Participants carried out the methods for this project as shown in Figure 3.1. Phases 1 and 4 were carried out by the Project Committee. Phases 2 and 3 were carried out by all participants in two workshops, which were held at the Delaware County Emergency Services Training Center near the Philadelphia International Airport in Sharon Hill, PA. Appendix B contains the agendas for the two workshops.

Phase 1: Problem Definition/Formulation

(Project Committee, pre-workshop teleconference/meetings: Feb. 13, Mar. 3, and April 15, 2015)

1. Assemble the Project Committee
2. Develop the scenario(s)
3. Estimate the transport, fate of oil, and exposure potential
4. Define response actions for consideration
5. Define resources of concern

Phase 2: Conceptual Model/Analysis Plan

(All participants, 1st workshop: June 9-10, 2015)

6. Consider important relationships
7. Thresholds of sensitivity to oil

Phase 3: Analysis and Risk Characterization

(All participants, 2nd workshop: June 23-23, 2015)

8. Determine levels of concern about effects
9. Evaluate relative risk for oil only vs. various response actions
10. Define limits of the analysis

Phase 4. Document and Apply

(Project Committee, post-workshop meeting: July 15, 2015)

11. Document the risk assessment
12. Apply the results in response planning

Figure 3.1. Sector DelBay CERA Process, 2015

The following modifications relative to the organization of previous ERAs were made to address the objectives of this project:

- This project was characterized by substantial and continuous engagement by members of the Project Committee that was needed to achieve the ambitious project objectives.
- In contrast to previous ERAs that involved one crude oil and two scenarios, this ERA evaluated two crude oils in five scenarios: Bakken (3 scenarios) and dilbit (2 scenarios).
- The five scenarios were defined for potential spills of different oils, in different seasons, and in different environments, i.e., freshwater, brackish, and salt water.
- Due to this complexity and the large number of participants, each workgroup evaluated and reached consensus among the workgroup participants regarding the potential risks of response actions for a specific scenario. This is a different approach than previous ERAs,

i.e., multiple workgroups evaluated the same scenario and a consensus among workgroups was reached.

- A new set of 10 categories of response actions was developed compared to the 3-4 considered in previous ERAs.
- Recent studies and other materials were compiled by the consultant team. These references were made available electronically to the Project Committee and workshops participants for their review through SRA's SharePoint. The list of these references is presented in Appendix C, Bibliography.
- Because these two crude oil types have the potential for significant flammability and other hazards when released in a transportation scenario, human health risks were considered in addition to ecological risks. Due to the flammability of these oils, fire fighters participated in this CERA and the ecological hazards associated with firefighting foam were evaluated in addition to traditional spill response actions, e.g., booms and shoreline cleanup.
- Due to the properties of these oils and the transportation routes considered (i.e., rail and marine intercoastal), a new set of response actions used in this CERA was developed.
- The resources at risk (RAR) included new socio-economic categories and freshwater, brackish water, and marine environments in the table.
- Presentations were added to the workshops to inform participants with leading edge information about these oils. Dr. Michel Boufadel of the New Jersey Institute of Technology, who is a National Academy of Sciences scholar appointed to the current study on "Effects of Diluted Bitumen on the Environment: A Comparative Study", gave a presentation on fate of these oils. Three presentations by industry representatives involved in crude oil transportation by rail as well as industry preparedness and response actions, including a Crude Oil by Rail Response Safety training course. This course, intended for safety staff and emergency responders, is available at http://www.api.org/oil-and-natural-gas-overview/transporting-oil-and-natural-gas/rail-transportation/crude-oil-by-rail-response-safety-course .
- This CERA considered the potential risk of response actions on federal and state listed T/E species in the vicinity of the five scenarios.
- Four subcommittees developed sets of essential background information that was presented and used in both workshops. The subcommittees and their leads were:
    - Oil Behavior, Transport, and Fate – Ed Levine and Frank Csulak (NOAA ERD)
    - Resources of Concern – Ben Anderson (DNREC) and Debra Scholz (SEA)
    - Effects – Clay Stern (USFWS)
    - Response Actions – Rich Gaudiosi (DBRC)
- The risk ranking matrix previously used to define thresholds of sensitivity to oil was modified to define the y-axis as a scale of the relative ecological impacts rather than estimation of the percent of resources impacted; new definitions of ecological severity were developed.
- Previous ERA projects had at least two workgroups separately evaluate the same scenarios, and then developed final consensus. The workgroups in this project each worked on separate scenarios. Consensus was reached within workgroups but not across workgroups about the relative risks of oil and response actions associated with the five scenarios.
- Workshop participants were asked to provide feedback on this process, both at the workshop and through an on-line survey.

3.1 Geographic Area of Concern

The geographic areas of concern for this CERA were the transportation routes of Bakken and dilbit oils in the Sector Delaware Bay AOR. These routes included barge and tanker marine transportation in the Delaware River and Delaware Bay, and 32 railroad crossings over creeks and rivers in the AOR. Sector DelBay identified 32 rail/water nexus areas in three states (Pennsylvania, Delaware, and New Jersey) and two federal regions (Regions II and III). From these 32 nexus areas, the Project Committee selected different environments (creek, river, and bay) through which Bakken and dilbit oils were transported by rail, barge, or tanker as being generally representative of the nexus areas. These locations served as the setting for the five scenarios identified for this CERA.

3.2 Scenarios

Following an initial kickoff teleconference on February 13, 2015, the Project Committee met on March 3, 2015 at Sector DelBay and identified five scenarios involving the two crude oil types that represented a range of situations in the AOR. The selected scenarios were located (Figure 3.2) in three different states (Pennsylvania, Delaware, and New Jersey) in two different federal regions, for urban and more rural environments, and two different seasons (winter and spring) to address the potential seasonal differences in response actions and sensitivity of RAR.

The spill scenarios were defined based on past incident history in the Port, potential impacts to natural resources, historical response actions, response assets within the Port, and the response strategies contained in the Sector Delaware Bay ACP (2012). Each of the scenarios is defined in Section 5.

Figure 3.2: Scenario Locations

Separate workgroups (consisting of Project Committee members and workshop participants) were organized to evaluate the risks of response actions for each scenario. Project Committee members, some of whom participated in the CERA previously conducted for Delaware Bay (Aurand and Coelho, 2006), were assigned to coach the workgroup participants in carrying out their assessment activities during both workshops. Recorders also were assigned to capture the discussion, assumptions, and results of the workgroups. The workgroup coaches and recorders were:

1. LCDR Weaver/A.H. Walker: Scenario 1 – Bakken Rail (Philadelphia, Schuylkill River - PA)
2. Rich Gaudiosi/Rebecca Weissman: Scenario 2 – Bakken Barge (Pea Patch Island, Delaware River - DE)
3. Debbie Scholz/Dave Pugh: Scenario 3 - Bakken Tanker (lower Delaware Bay - DE)
4. Clay Stern/Melinda McPeek: Scenario 4 – Dilbit Rail (Mantua Creek, NJ)
5. Ben Anderson/Stacey Burger: Scenario 5 – Dilbit Barge (Marcus Hook anchorage, Delaware River - PA)

The following sections describe the sets of RAR and response actions evaluated in all five scenarios. In most of the previous ERAs, a single conceptual model and modeling could be discussed in one section because the main variable of comparing ecological risk was the volume of oil spilled, e.g., large vs. smaller spill. However, in this project, the scenarios are so different from one another that separate models were run for each scenario and separate, scenario-specific conceptual models also were developed.

3.3 Resources at Risk

The Project Committee developed the following list of resources of concern and at risk in the five scenarios, grouped according to habitat, sub-habitat, and resource categories.

Habitats:

- Artificial shorelines
- Natural terrestrial shorelines
- Intertidal shorelines (including surface waters 0-1 meter)
- Mid-water (0-2 meters above the bottom)
- Benthic (bottom + 2 meters)

Sub-habitat:

- Bulkheads, riprap, manmade structures, pavement
- Vegetated, sand, gravel
- Marsh, swamp, tidal flats
- Water column
- Seabed
- Socio-economic resources
- Human health receptors

Categories of Ecological Resources of Concern:

- Mammals (aquatic and non-aquatic dependent)
- Birds (aquatic and non-aquatic dependent)
- Reptiles and amphibians (aquatic and non-aquatic dependent)
- Macro-invertebrates
- Aquatic vertebrates
- T/E species – Animals
- T/E species – Plants
- Plants (submerged and floating aquatic vegetation)
- Fishing (commercial and recreational)
- Water intakes (surface and mid-water)

Categories of Socio-economic Resources of Concern:

- Workers
- Residential community
- Sensitive receptors
- Commercial community
- Industrial community
- Transportation community

A draft RAR table was presented at the first workshop, discussed and accepted with some specific examples appropriate for each scenario. For example, the examples of RAR in the urban, river environment of Scenario 1 (Philadelphia, PA) are different than the specific examples for a creek in an industrial area (Mantua Creek, NJ). The actual RAR associated with each scenario varied given the seasonal differences in scenarios (winter vs. spring), e.g., diamondback terrapins hibernate during winter and are at less risk from some response actions than other times of year.

The final consolidated RAR table for all five scenarios is presented in Appendix D. This table presents examples of plants and animals that could be present in any season and life stage, rather than limited to only those that are present on the dates of the scenario. Examples of both federal and state T/E species are included. The habitats for the scenarios spanned freshwater (Scenarios 1 and 4), brackish water (Scenarios 2 and 3), and saltwater environments (Scenario 5).

The presence or potential presence of different protected species, i.e., federally and state listed threatened and endangered plants and animals, also varied somewhat among scenarios. Although omitted from the endangered species list of examples in this ERA, seals, beluga whales, and manatees (protected under the Marine Mammal Protection Act of 1972) have occasionally been sighted in the AOR. For example, manatees were sighted in NJ in 2009 and again in the Delaware River north of Philadelphia in 2015 (Philly.com, 2015).

3.4 Response Actions

In pre-workshop meetings on March 3, 2015 and April 14, 2015, the Project Committee reviewed recent literature and spill reports about Bakken and dilbit oils, including oils that have similar properties, and then the Committee compiled a detailed list of potential actions that could be appropriate to implement during response to these oils. Due to the already ambitious project

objectives, the Committee decided to omit Subpart J[6] response options from consideration for this ERA. This overall list was then categorized to better align with the response categories of previous ERAs and to facilitate evaluating their risks. These general categories provided a common framework for the workgroups since specific response actions could vary among the five scenarios, e.g., some on land, some on water, and presence or absence of ice.

The following categories of actions were used in assessing the risks associated with responding to Bakken and dilbit oil spills in the five transportation-related scenarios:

1. No response action – Natural attenuation of oil with monitoring
2. Fire – Let burn and controlled burn (both in-situ)
3. Fire – Extinguishing agent and methods
4. No Fire – Vapor suppression
5. No Fire – Oil spread control, on land, on water, and underwater
6. No Fire – On-water recovery and underwater recovery
7. No Fire – Resource protection, on water and on land
8. No Fire – Shoreline cleanup
9. No Fire – Oil detection/mapping (physical contact methods)
10. No Fire - Oil detection/mapping (remotely observed methods)

Appendix E presents the final set of response actions in a table used by workshop participants to characterize the risks of response actions in the five scenarios. The table defines the response actions, provides examples of them along with their associated logistical considerations, and summarizes their respective constraints and estimated, generalized levels of effectiveness in identified habitats.

The list of response actions takes into account that response to these crude oils involves two phases: the initial flammability phase when light ends of the oils are present and fires could occur, during which the deployment of traditional spill response options would be pre-empted by first responder (fire fighter) actions; and a second, longer-term phase of responding to the oil on-water. Fires have resulted following recent incidents involving Bakken oil, which has been known to re-ignite. Flammability is also a concern with freshly-spilled dilbit oil. These acute public safety concerns take precedence over pollution response. The time scales associated with the phases are not absolute; rather they represent a range of hours and days that generally align with important weathering and behavior changes that would influence decisions about response actions. For purposes of this ERA, ***Phase 1 covers approximately the initial 4-6 hours***; long enough for pollution responders to become actively engaged after first responders (e.g., fire fighters) have arrived on scene and probably would still be dealing with flammability risks. ***Phase 2 includes the time after the initial 6 hours, but focuses specifically on the timeframe when the oil behavior on the water could begin to change and requires different response strategies***, which participants estimated to be ***about 4-7 days into the spill***.

For both of these crude oils, oil recovery is difficult in the second phase. Bakken oil is a light crude oil. Following rapid evaporation of light ends, the remaining components naturally disperse into the water column, making recovery from the water generally impractical. Dilbit oil, on the other hand, comprises heavy oil tar sands mixed with diluents to facilitate its

[6] http://www2.epa.gov/emergency-response/national-contingency-plan-ncp-subpart-j-product-schedule-fact-sheet

transportation. When initially spilled, the diluents begin to separate. After a few days, residual heavier components may be exposed to sediments in the water column, no longer float, and then become difficult to track and recover.

Although (intentional) controlled burning *in situ* was discussed and left as an option, there is no fire boom available in port. If burning became a preferred option in Delaware Bay, fire boom would have to be brought in and the logistics and approval would likely preclude its implementation. Also, air quality becomes an issue with burning Bakken oil, e.g., concerns about breathing in the toxins that are in the resultant smoke plume.

The DBRC recently formed an industrial fire group to share fire resources among member companies. The Fire Chief from Sunoco Logistics presented information on fire-fighting foam in the port to participants in the June 9-10 workshop. The highlights from this presentation include:

1. The use of foam to manage flammability hazards and fires was the subject of considerable discussion. Using enough foam to blanket vapors and extinguish fire is a fire safety goal, but applying enough foam to prevent re-flashing is almost next to impossible. Bakken is very likely to re-ignite.
2. There were also questions regarding the expiration dates of stockpiled foams. The expiration dates for most foams are about 20-25 yrs. from the date of manufacture when properly stored. The foam should be tested regularly, with annual testing being ideal.
3. Foam purchased from the manufacturer is actually in concentrate form. It must be mixed with water and air to become a foam solution. It is not foam that extinguishes fires—it is the water component and access to abundant source of water is needed to put out a fire. In the marine environment, responders have access to plenty of water, but they may lack access to the necessary platform and hoses, which is also essential.

Spills and fires outside of the normal realm, i.e., along a transportation route, are problematic for industry to provide assistance. Coordinating the logistics to mobilize the necessary resources to the response (oil spill or fire) and set up when a fire occurs off-site, outside a facility where the foam is stored, takes time. The challenge is getting the water, tools, and foam to a fire on a barge or tanker away from a dock in time to reduce fire hazards. This resource/logistical coordination is also time consuming for a rail car incident, since these incidents rarely occur in geographically convenient locations relative to where foam is stored. Certain foams require specific nozzle equipment that further complicates response logistics. It should be noted that in many fire-fighting scenarios, the approval for using fire-fighting foam is contingent upon the containment and disposal of fire-fighting wastes (foam and water). This would be a challenging requirement in a marine environment.

The runoff from fire-fighting foam if applied in the five scenarios could present both human health and ecological risks. Older-generation foams contain Perfluorochemicals (PFCs), which have been commonly used to improve the ability of fire-fighting foam to smother fire. The EPA is phasing out the use of PFCs, as its use can result in a water quality issue and it can also be dangerous to aquatic life and human health. In particular PFOS (perfluorooctane sulfonate) and PFOA (perfluorooctanoic acid) are two commonly used PFCs that are known to enter ecosystems and move up food chains, accumulating in animal and human tissue, including the liver and blood.[7] PFCs have been linked to bladder and liver cancer, endocrine disruption, and

[7] http://www.crccare.com/case-study/fighting-fire-fighting-foam

developmental and reproductive toxicity, including neonatal mortality and are potentially lethal to animals.[8] PFOS and PFOA are increasingly being phased out of modern foams. Additionally, all fire-fighting foams (including the modern foams that do not contain PFCs) may cause a decrease in water oxygen content that can have a negative effect on water quality and aquatic ecology. It appears from reviewing the foam Material Safety Data Sheet (MSDS)[9] (Appendix F) that PFOA and PFOS are not present in these three foams. However, it is unknown if these are the only foams stored in the port area. Two of the three foams reviewed did contain fluorinated surfactants at low levels. Evidence for shorter-chain fluorinated compounds behavior in the environment is limited, and further research is needed as production of other fluorinated compounds increases as an alternative to PFOA and PFOS in fire-fighting foams (Scheringer et al., 2014). While research has generally shown that shorter chain fluorinated compounds are less toxic and less bio-accumulative, some research has shown that some shorter-chain fluorinated compounds can biodegrade into persistent organic compounds (Scheringer et al., 2014; Queensland Incident Response Unit, 2014).

3.5 Conceptual Models

The workshop participants reviewed the conceptual model presented in matrix format that was prepared for the San Francisco Bay workshop (Pond *et al.*, 2000) and used in previous ERAs. Participants updated and expanded the definitions of potential hazards to align better with the five scenarios.

The definitions of hazards used in completing the conceptual models for each of the scenarios are:

1. Air pollution – vapors, direct effects from respiratory issues for air breathers. Therefore, air pollution is not a stressor for mid-water, benthos.
2. Aqueous exposure – direct effects from aquatic respiration and dermal exposure to oil and oil components dissolved within the water column; may be short-lived exposure with the potential for high consequence for impacted species. Excludes submerged oil globules.
3. Physical trauma (mechanical impact from equipment, aircraft, people, boats, etc.) – direct effects from physical impact on individual species, including disturbance.
4. Oiling/smothering – direct effects from dermal contact with oil; skin (hypothermia), mucosal membranes (eyes, nares, etc.); indirect effects or secondary impacts could include ingestion (preening). May include contact with submerged oil globules or mats.
5. Thermal (heat exposure from fire) – direct effects from oil burning; impacts from exposure to a fire/burn (not dermal exposure to the oil).
6. Waste – direct effects prior to being removed (pre-cleaning) from the system. Excludes equipment intended for re-use, e.g., non-sorbent boom.

[8] Betts, KS (2007). 'Perfluoroalkyl acids: what is the evidence telling us?', *Environmental Health Perspectives* vol. 115, iss. 5, pp. A250-256.

[9] The MSDS was part of OSHA's Hazard Communication Standard (HCS). However, the HCS has been revised by OSHA to align with the Globally Harmonized System of Classification and Labelling of Chemicals (GHS), GHS and one change is the renaming of MSDSs to simply safety data sheets, or SDSs. Since most of the data sheets used in the ERA still carry the MSDS label, they are referred to in the report as MSDS.

7. Ingestion (food web, etc.) – resources indirectly exposed to oil or its constituents via ingestion of oil or contaminated/affected prey.
8. Advisory/Closure – prohibited action of use (e.g., commercial or recreational fishery, water intake); protection from possible exposure.

Recognizing the distinctive oil behaviors of Bakken crude and dilbit oils, the conceptual models developed for these oils reflect the two phases of potential exposure pathways:

- B1 = Bakken on the water/soil surface (initially)
- B2 – Bakken within water column due to natural dispersion (later)
- D1 = Dilbit before weathering (initially)
- D2 = Dilbit after weathering (later)

The conceptual model developed for this CERA depicts the connections between the resources of concern (human health/socio-economic and ecological) and their potential to be exposed to hazards (exposure pathway) for five scenarios. The numbers in the cells (1-8) represent the path by which a hazard can affect a resource. The completed model for each scenario represents the record of the reasoning of each workgroup about the concern for that resource. ***NA*** represents the absence of a connection between a potential hazard and the resource of concern.

Appendix G contains the completed conceptual models for human health and safety (some but not all workgroups completed them) and five ecological models for different scenarios (all workgroups completed these separately).

3.6 Modeling Results

This CERA considered the properties, behavior, and hazards associated with both oil types from the initial release through approximately seven days. Modeling of the spilled oil on water was conducted for all five scenarios by NOAA. A smoke plume model (Interagency Modeling and Atmospheric Assessment Center) also was run for Scenario 1, since that scenario resulted in a fire almost immediately. This plume model provided information about the footprint of the smoke plume in relation to human health and socio-economic resources at risk. Additional models that can be run, but were not for this CERA, are those that estimate concentrations and size of flammable vapor cloud, including SAFER, CHARM, and ALOHA.

For the oil spilled into waterways, basic weathering information and an oil budget (amount spilled, evaporated, naturally dispersed, remaining) along with individual trajectory models were calculated for each of the five scenarios. The NOAA Emergency Response Division (ERD) Modeling Group used the basic information in the scenarios to develop a surface trajectory analysis using GNOME[10] (General NOAA Operational Modeling Environment) for the detailed risk assessment portion of the workshop. Basic weathering information was calculated using the ADIOS 2[11] program. The model was run to show extent of contamination from the start of the

[10] GNOME is the modeling tool that OR&R Emergency Response Division uses to predict the possible route, or trajectory, a pollutant might follow in or on a body of water, such as in an oil spill

[11] ADIOS (Automated Data Inquiry for Oil Spills) is NOAA's oil weathering model. It is an oil spill response tool that models how different types of oil weather (undergo physical and chemical changes) in the marine environment (http://response.restoration.noaa.gov/adios).

incident (zero hours) through about 4 days. The modeling results were used to characterize the risks associated with each of the scenarios, which is discussed in Section 5.

The weathering and modeling results, e.g., graphic plots, are presented in Appendix H. The information for each of the five scenarios includes: the ADIOS 2 weathering and oil budget tables up to 120 hours following the initial discharge, screenshots at different times (e.g., +1 hr., 5 hrs., 14 hrs., 18 hrs., 36 hrs., and 42 hrs.) from the GNOME trajectory model, and extent of oiling maps for the first four days of the incident. The screen shots were selected to illustrate noteworthy stages of oil movement for each scenario; they were not selected to be comparable across scenarios. With regard to oil weathering/behavior and pollution response actions, actionable oil will be in the environment approximately 4-7 days following the initial discharge. Between 12 and 48 hours, the oil budget tables indicate that 56 to 61% of the Bakken oil remains in the environment. For the dilbit scenarios, between 12 and 48 hours, 75 to 77% of the oil remains in the environment.

Evaporation of the light components of both oils occurs rapidly in the first 12 hours and during this time, flammable vapors and benzene would be a distinct health and safety concern for both oils. In particular, the flammable vapors and no-fire situation are potential barriers to implementing pollution control options due to their ignition hazard.

The time-weighted average limit (TWA) limit for benzene is 1 ppm over an 8-hour period; the short-term exposure limit (STEL) is 5 ppm for a 15-min period. Personal protective equipment (PPE) can be used to protect workers but large spills of these oils near public communities could require evacuation. Since evacuation is in the jurisdiction of local authorities, evacuation is not a response action available to the USCG and was omitted from this ERA.

3.7 Risk Ranking Matrix

The Effects Subcommittee lead reviewed the risk matrix from previous ERAs and proposed a modification that would improve its utility for characterizing threshold levels of concern for the impacts of Bakken and dilbit oils in the five scenarios. ***Risk*** is defined as the probability of an impact occurring; participants must qualitatively consider if there is a high, medium, or low probability of the impact occurring, and then determine the severity and the duration of the impact. The conceptual model is the first step in considering the risk of potential exposure of a resource to the spilled oil.

The Effects Subcommittee lead reminded participants that the risk characterization of a CERA is qualitative, not quantitative, in nature. Quantitative risk assessments that focus on the actual injury to the environment (habitats and organisms) are carried out following an oil spill through Natural Resource Damage Assessment (NRDA) activities. ***Injury*** is a legal term defined in the OPA 90 (Oil Pollution Act) regulations and under CERCLA. Injury is defined as a linkage between cause and effect beyond a reasonable doubt. When working during response, responders tend to consider and decide about impacts that are relatively short-term and based upon what was learned from previous response events, e.g., it is better to protect marshes to avoid having them oiled because of the longer-term severity and duration of oil impacts in those environments. The response community now recognizes that protecting marshes from oiling is a response best practice; this knowledge guides preparedness and response decisions, without a NRDA study.

The revised matrix enabled workshop participants to more readily assess potential risks using the best available information from literature (e.g., the references in Appendix C), past experience with oil spills in the area, e.g., the *M/V Athos* in 2004, and their knowledge of resources in the AOR. It also reorders the presentation of levels of concern from lowest (green on left side of the matrix) to highest (red on the right side).

The updated risk matrix is presented in Figure 3.3. Workshop participants approved this risk ranking matrix during the June 9-10, 2015 workshop.

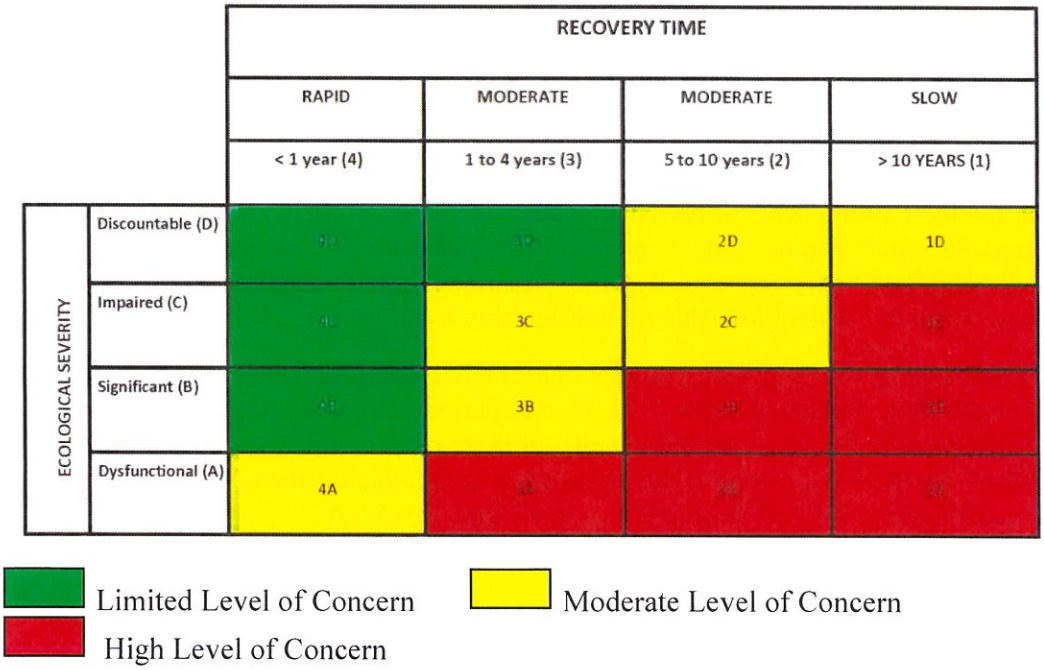

Figure 3.3 Levels of concerns risk matrix for the 2015 Sector DelBay assessment

The definitions of ecological severity used by participants in assessing risk in this CERA are:

- **Discountable** – Impact considered negligible, trivial, or a minor inconvenience, e.g., birds flew off nest but came back and landed.
- **Impaired** – Animal or community feels an impact; it may not be terribly significant or long-term, but it is an impact.
- **Significant** – Effects that are potentially life altering or may disrupt a breeding cycle; those that can affect community, e.g., all blooms knocked down, impacts reproductive cycle.
- **Dysfunctional** – Juveniles wiped out, habitat completely smothered, reproductive cycle severely impacted (not occurring/ceased); adults wiped out.

Workshop participants used this risk ranking matrix during the June 23-24, 2015 workshop to estimate the level and duration of ecological impact of the response actions compared to the impact of the spilled oil alone. Duration of impact begins from the time of the oil discharge. Severity takes into account the significance of individual organisms relative to the scale of population. For example, if an organism had recovery about 70% one year, but would take 10

years for 100% recovery, then the risk could be ranked as significant, in the 1- to 4-year duration. Local populations that could be killed by a spill would receive a dysfunctional score. Freshwater mussels, for example, if wiped out by oiling in a creek, will not recover for 50-100 years. This would equate to a risk of a dysfunctional impact. Generally, participants considered populations of organisms at the local scale, and assumed no impacts on a regional or national scale for that species.

For an endangered species, any harm qualifies as a ***take***[12] and is significant. As generally applied in this ERA, non T/E plants would recover in 4 to 5 years and non T/E fish would recover in 1 to 2 years. The ranking of red does not mean to stop actions, but rather to review and assure that response actions would not adversely affect the species of concern.

The ranking measures were also appropriate for characterizing human health risks. The impact from a drinking water ban would likely be considered *Dysfunctional* in severity; inhalation and dermal impacts might be ranked as *Significant*.

Participants used the information available to them to assign levels of concern about the risk. The information gathered for participant review before and between the workshops is presented in the Bibliography (Appendix C). As can be seen in the risk matrix, the groups used alphanumeric scores to scale the anticipated impact severity and recovery time. After developing the scaling, color coding was used to indicate the summary levels of concern. The risk scores represent a consensus on the part of the participants that such consequences were likely to occur under the scenario under consideration.

[12] ESA, Section 7, and Incidental Take of Endangered and Threatened Species in U.S. Lands or Waters. Being listed on the ESA makes it illegal to "take." Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, collect, or attempt to do these things (50 CFR § 3(19), 2009) any of these protected species, whether endangered or threatened or adversely modify or destroy designated critical habitat under Section 9 – Prohibited Acts. NOTE: Under ESA, 'take' prohibitions under Section 9 are not automatic for threatened species; the USFWS and NMFS must conduct a Section 4 process to address threatened species.

4.0 Results

The summaries of the risk characterizations for each of the five scenarios are presented in Figures 4.1 (Bakken oil scenarios) and 4.2 (Dilbit oil scenarios). Scenarios 1-3 involved Bakken oil; Scenarios 4-5 involved dilbit oil. As noted earlier, unlike previous ERA where at least two workgroups separately evaluated the same scenarios and then developed final consensus, the workgroups in this project each worked on separate scenarios. That is, the findings presented here summarize the workgroup-specific consensus for Scenarios 1-5, rather than consensus of all workgroups about all scenarios. For the reader's convenience, a row that highlights the transportation setting (i.e., urban, creek, river or bay) of each of the scenarios has been added to the summary tables.

Both Bakken and dilbit oils are characterized with flammability hazards during the early stages of a spill. Some recent Bakken oil rail incidents have resulted in fires, e.g., in the town Lac-Megantic, Canada (2013), which resulted in 47 deaths from the burning oil when the train derailed while passing through the center of the town. The risks to human health and safety and social-economic resources from a fire as well as fire-fighting foam, as highlighted in Scenario 1, were scored as a moderate level of concern (yellow) assuming that safety measures were successful, e.g., PPE for workers and other protective measures for the public, such as safe distance from fire and shelter in place away from the smoke plume. For human health and safety, the levels of concern from the oil only and for other response actions were scored as low (green).

The presence of a red ranking (high level of concern) represents a need for follow-up action by the Area Committee and Regional Response Team to more fully address whether certain response actions will be allowed and if so, under what circumstances, e.g., in certain seasons or under specific conditions. The red ranking of highest relative risk is not intended to prevent or stop response actions, but rather to prompt further review and assure that response actions would not adversely affect the species of concern.

The gray cells scored "Not Applicable" refer to the absence of either the resource at risk in a scenario or the lack of pathway for exposure to the hazard presented by the oil or type of response action during Phase 1 or Phase 2. For example, in Scenario 3, which involves a spill of Bakken oil in the middle of the upper Delaware Bay in winter, during the first 4-6 hours, the risk to shorelines and benthos were scored as Not Applicable because the oil would not reach those environments in that time frame.

In this CERA, participants assigned higher levels of concern about the ecological risks associated with a spill of dilbit oil compared to a spill of Bakken crude oil.

4.1 Bakken Oil Response Actions

Scenario 1 occurs from a rail crossing within Philadelphia's urban setting; Scenario 2 involves a barge in the middle of the Delaware River near Pea Patch Island, an ecologically and culturally-sensitive resource; and Scenario 3 involves a tanker in the open water of upper Delaware Bay.

In general, the workshop participants from Scenarios 1, 2, and 3 found that the "No Response other than monitoring" option was considered of limited or moderate level of concern when deemed appropriate for the scenario conditions, both at the 4- to 6-hour response frame or at 4 to 7 days post discharge. In most cases, the participants found that there was very little change

in concern levels when considering the various response action versus the "no response" action. Although some of the levels of concern did increase from low to moderate (green to yellow), this increase in concern did not require a change in response options. The highest level of concern in the urban, freshwater scenario (1), was with the use of extinguishing agents or for vapor suppression in the intertidal zone for both the initial response and over the 4- to 7-day response times.

Overall, the highest level of ecological concern (red) in these scenarios occurs from the risk of the use of fire-fighting foam as a fire extinguishing or vapor suppression agent to threatened/endangered species, which may be present in Scenario 1 intertidal shoreline. The use of foam in this area in both response phases increased the risk (yellow) over the presence of oil only (green).

In the initial 4-6 hours after a Bakken spill occurs in these scenarios, the response actions that ***positively change, i.e., decrease the risk (change a yellow to a green score)*** compared to the "no response other than monitoring" actions are:

- Scenario 1 – oil spread control, on-water recovery, resource protection, shoreline cleanup, and remotely observed oil detection/mapping in the mid-water habitat (Scenario 1)

In the initial 4-6 hours after a Bakken spill occurs in these scenarios, the response actions that ***negatively change, i.e., increase the risk (change a green to a yellow score)*** compared to oil only are:

- Scenario 1 – oil spread control, on-water recovery, resource protection, shoreline cleanup, and remotely observed oil detection/mapping in natural terrestrial shorelines.

In Scenarios 2 and 3, implementing response actions does not noticeably decrease ecological risks compared to the risk of oil alone.

After the oil has been in the environment for 4-7 days, much of the Bakken oil would have weathered, leaving a light residual oil staining on shorelines, including the intertidal portion of the shoreline, which could be below the water surface (surface water or mid-water column habitats @ 0 meters) during high tide.

After the oil has been in the environment for 4-7 days, the response actions that ***positively change, i.e., decrease the risk (change a yellow to a green score)*** compared to oil only is:

- Scenario 2 – implementing on-water oil recovery near intertidal shorelines.

After the oil has been in the environment for 4-7 days, the response actions that ***negatively change, i.e., increase the risk (change a green to a yellow score)*** compared to oil only are:

- Shoreline cleanup in artificial shorelines and natural terrestrial shorelines in Scenarios 1 and 2.

4.2 Dilbit Oil Response Actions

Scenario 4 occurs from a rail crossing over Mantua Creek in New Jersey; Scenario 5 involves a barge in the middle of the Delaware River near the Marcus Hook Anchorage. Generally, the ecological risks associated with spilled dilbit oil and the anticipated response actions for the two scenarios are either moderate or high level of concern, especially if T/E species are present in contaminated areas.

As with Bakken oil, the highest level of concern (red) in these scenarios occurs with threatened/endangered species, which may be present and could be impacted by the oil and/or response actions. In these scenarios, T/E species (e.g., Atlantic sturgeon to sea turtles to bald eagles) might be present and at risk in all environments except artificial shorelines.

In general, the workshop participants from Scenarios 4 and 5 found that the "No Response other than monitoring" option provided a moderate to high level of concern, both at the 4- to 6-hour response timeframe to 4 to 7 days post discharge. In most cases, the participants found that there was very little change in concern levels when considering the various response action versus the "no response" action. Some of the levels of concern did increase for response actions over the 4- to 6-hour timeframe to the 4- to 7-day period from low to moderate (green to yellow). The high level of concerns (red) were scored for scenario 5 regarding the use of most response options deemed applicable for use in the intertidal, mid-water, and benthic zones for both the initial response and over the 4- to 7-day response times. Similar concerns were also expressed for Scenario 4 when considering the risk of shoreline clean up and oil detection / mapping methods for the intertidal and midwater zones.

In the initial 4-6 hours after a dilbit spill occurs in these scenarios, the response actions that ***positively change, i.e., decrease the risk (change a yellow to a green score, or a red to a yellow score)*** compared to oil only are:

- Scenario 5 – oil spread control and on-water recovery in artificial shorelines and at the water's edge (0 meters of the mid-water habitat); and resource protection in intertidal shorelines

In the initial 4-6 hours after a dilbit spill occurs in these scenarios, ***no response actions negatively change, i.e., increase the risk (change a green to a yellow score, or a yellow to a red score)*** compared to the presence of the "no response" action only.

It is important to note that in some habitats, oil detection and mapping methods (if physically disturbing) were scored as a higher risk (red) than oil spread control, on-water recovery and resource protection to natural vegetated shorelines, intertidal shorelines, and mid-water habitats (yellow or green). Remotely observed methods would present a low (green) ecological risk. Participants recognized that available methods to detect and recover submerged dilbit oil are lacking in effectiveness.

Workgroup participants noted that on-water oil recovery in the earliest stage after release is the most important response action to prevent the oil from spreading out and expanding the extent of contamination, e.g., into the Delaware River, and contaminating larger shoreline and benthic habitats and organisms. This oil type will transform from a fairly light crude-like product to a heavy #6 product that will be tacky and adhesive. The oil will likely behave differently as it

weathers in ambient conditions; it could behave as one type of weathered product and a different type a few hours later. This was the situation with the oil spill from the M/V Presidente Rivera in 1989, which required one set of tactics in the morning and a different set in the afternoon because the pour point of the oil was just above or below ambient air and water temperatures.

After the light ends of the diluent have flashed off, the residual product will be extremely tacky and will adhere to whatever it contacts. From an environmental standpoint, this is a significant challenge for onshore cleanup and wildlife rehabilitators to avoid if at all possible. It will take time to experiment (trial/error) with emerging ideas and techniques and develop new response/restoration best management tactics to manage dilbit releases.

After the oil has been in the environment for about 4-7 days, much of the dilbit oil would have weathered to the point that the diluent evaporated, leaving the heavier, persistent bitumen in the environment, available to pick up sediments and sink to the benthos.

After the oil has been in the environment for 4-7 days, the response action that ***positively changes, i.e., decreases the risk (change a yellow to a green score)*** compared to the remaining oil (NAM only) is:

- Scenario 4 – controlled in-situ burning in natural terrestrial shorelines, intertidal shorelines, and the water's edge of the mid-water habitat (0 meters).
- Scenario 4 - oil spread control, on-water recovery, resource protection, shoreline cleanup in natural terrestrial shorelines
- Scenario 5 – Resource protection in intertidal shorelines.
- Scenario 5 - oil spread control, on-water recovery the water's edge of the mid-water habitat (0 meters).

After the oil has been in the environment for 4-7 days, the response actions that ***negatively change, i.e., increase the risk (change a green to a yellow score)*** compared to oil only are:

- Scenario 5 - shoreline cleanup in artificial shorelines (increased risk to reptiles, amphibians, and macro-invertebrates).

4.3 Additional Findings and Observations

- The high level of engagement by members of the Project Committee strengthened the consensus value of the outcomes.
- Participants recognize that the potential risks of the oils and response options could vary from the ERA findings during an actual spill, depending upon exact location in proximity to sensitive resources of concern and time of year.
- The summary tables presented in Table 4.1 and 4.2 might be viewed as "dashboard indicators", that is, metrics and key performance indicators for operational dashboards that are viewed as an effective means of alerting decision makers as to where they are in relationship to their objectives.
- When scored green, the response actions listed on the left side of the table represent the workshop participant recommendations.
- When spilled, Bakken and dilbit behave differently. Moreover, the behavior of dilbit oils can vary depending upon the type and percentage of added diluents. For Bakken oils, participants agreed that the primary initial strategy is to safely mitigate risks from flammable vapors. For dilbit oils, participants determined that it is imperative for containment and skimming operations to be implemented immediately to recover the oil before it spreads, weathers, begins to pick up any sediments in the water, and possibly would begin to sink. In a creek, the primary recovery strategy would be skimming before the oil can move into the river. However, in developing response strategies during the initial hours of a spill, responders must also consider health and safety hazards of the oils, i.e., evaporation of light ends, release of hydrogen sulfide gas, and flammability, especially with regard to the ignition sources, e.g., boat engines.
- Uncertainty exists around the use of fire-fighting foam.
- An important take away is the long duration of recovery for freshwater mussels in Scenario 4.
- In Scenario 2, it is best to keep the Bakken mid-river away from shorelines, but this would be problematic, given the flammability/ignition issues associated with boat engines and securing the source to limit the volume of the spill, stabilizing the vessel, and implementing containment near the source.
- Participants would like to know more about any studies conducted on the vapor density off-gassing.
- Participants noted the need to carry LELs on the OSRVs.
- Participants requested additional research/studies conducted on the vapor density, particularly how high above the surface the vapors were likely to be present, and noted the need to carry LELs on the OSRVs.
- Participants identified the need to have further study of the potential water column concentrations and toxicity of foam if applied in coastal (marine, estuarine) waters.
- Participants noted that R&D is needed to improve the ability to recover submerged dilbit oil, which is persistent, without damaging the habitats and organisms, especially those that have a long period of recovery, such as the freshwater mussels in Mantua Creek and T/E or rare species. Some of the recent R&D work by Dr. Boufadel, among others, is

increasing our understanding about dilbit behavior and fate, and may provide new insights for early response and potentially treatment to reduce its persistence.

- One gap in the assessment concerned Section 106 of NHPA, to involve State Historic Preservation Officer (SHPO) and HPA, and to look at tribes in the AOR and their preferences for consultation. Activities to address this gap are underway in the Region but were not resolved in time to incorporate in this ERA.
- Workgroup participants identified an information gap with regard to estimates of fish and bird populations in the area, which increased uncertainty around severity estimates.
- Participants using the NOAA ESI maps did not seem cover the full range of environmental resources at risk in all scenarios, e.g., freshwater mussel beds in vicinity of Mantua Creek. NOAA responded that east of Mantua creek there is a mapped a record of the NJ ST eastern pond mussel. It is important to recognize that NOAA focuses on state and federally-listed species, not necessarily all 'rare' species. In addition, NOAA is not always provided with data for all records or species for every state, rather the exact records are at the discretion of the data provider. Data for New Jersey was provided by NJDEP Endangered and Nongame Species Program in 2013.

4.4 Recommendations

The Project Committee evaluated oil spill response strategies identified during this process through literature review and informed by open dialogue among oil spill planners, managers, responders, and natural resource trustee agencies. The output of this risk assessment is intended to enhance existing oil spill area contingency planning. Participants looked at the net benefit of the response action to determine if it made the situation better or worse than the no active response other than natural attenuation and monitoring.

Since this CERA was adapted to address a broader scope than previous ERAs, participants were asked to provide feedback on the workshop process, following the second workshop. A summary of their comments is presented in Appendix I.

Participants made the following recommendations to Sector Delaware Bay, in no particular order:

- Begin working with port partner subject matter experts to apply these results to develop a set of BMPs to guide FOSC decision-making during preparedness and response for spills from these transportation scenarios, along the lines of the NOAA Shoreline Countermeasure Manual.
    - If possible, develop recommendations for a holistic "concept of operations" approach for dilbit oil spills. That is, a priority sequence of response actions to implement near the spill source. For example, focus on pre-spill planning to improve the effectiveness of oil containment and recovery in the early stages of a spill. The best option to minimize the ecological risk of this crude oil using current technology is to deliver containment and recovery equipment faster to the scene to limit the geographic spread of oil, and recover the majority of spilled oil, before weathering when the oil would submerge and become more difficult to detect and recover.
    - In the Scenario 4 workgroup, for example, the participants strongly believed that the key to reducing ecological risks would be to contain and recover the

oil almost immediately near the spill source, which they also recognized would be highly unlikely.
    - As appropriate, generic, key topic areas should be developed into best BMPs presented in tabular format or list and incorporated into the ACP. For example:
        - Protect sensitive shorelines
        - Booming: does not represent a concern unless actions drive oil into mudflats or if T&E species are impacted by deployment actions.
        - Removing oil residue from shore: does not represent a concern unless actions drive oil into mudflats or if equipment impacts T&E species.
        - On water skimming: does not represent a concern.
    - One option is translating the summary matrices into GRS, when to use these response actions (green), when not to use (red) and those that need more consideration (yellow).
- Before commencement of emergency response actions, threatened and endangered species require an informal consultation with services before it is assumed they are not present.
- Future ERAs should assess the potential risks and net environmental benefit of response actions that involve materials regulated by Subpart J of the National Oil and Hazardous Substances Pollution Contingency Plan, e.g., Imbiber Beads.
    - Also, explore the potential use of helicopter-deployed herder agents for Bakken spills in open water, similar to Scenario 3, and consider a test zone and window of opportunity.
- Future ERAs should consider the viability of developing a single conceptual model for these two types of crude oil. This project developed five that are slightly different from one another because there was inadequate time for five workgroups, 90 participants to reach consensus on a generic conceptual model in this ERA.
- It would be useful to conduct future ERAs on similar scenarios in temperate climates but with different seasons. For example, Scenario 4 would likely have had different outcomes if the same volume of oil had been discharged in spring and closer to Delaware.
- Participants would like EPA to consider investigating water column concentrations and dilution of foam in its testing of Bakken oils at OHMSETT in New Jersey.
- Participants recommended that issues on the use of foams and hazards associated should be added to the ACP, including:
    - Confirm whether or not fire-fighting foams containing PFCs are being stored in the area.
    - Assess the feasibility of logistical actions and coordination needed to enable the use of foam in mitigating risks from hazards during rail, barge, or tanker response.
    - Evaluate the approval/authorization issues for applying fire-fighting foam for crude oil incidents that threaten navigable waters. Do human health and safety priorities negate the need for RRT approval? If RRT approval will be necessary, define the preparedness actions to enable approval when needed.

5.0 Discussion

As noted earlier, participants reviewed and approved a revised risk matrix for use in this project (Figure 3.3). For each scenario, workgroup participants completed a conceptual model, and then reviewed information on the oils, their properties (Appendix C), MSDSs on three types of firefighting foam (Appendix F), weathering and trajectory modeling results Appendix I), ESI maps showing the location of RAR in relation to the projected extent of contamination, T/E species lists and map of water intakes from the ACP, other relevant information about seasonality and distribution, plus case studies and spill reports involving these or similar oils. Because of the differences among the scenarios, including the assumptions made for each, the summary results of the risk characterizations for the five scenarios are discussed separately. Participants generally conducted a conservative evaluation and recognized that these findings could be less conservative in an actual situation.

The conceptual models were used first to clarify the pathways of exposure and the types of hazards between the spilled oil and seasonally-present RAR. The risk matrix was first completed by each workgroup to characterize the risks to resources of concern from the oil only, i.e., no response action, except for natural attenuation and monitoring (NAM). Next, participants compared the potential risks of each category of response actions to the risks associated with the spilled oil left in place to attenuate, plus monitoring via sampling. During this comparison, participants were asked to determine:

1. If using a response action is likely to ***improve*** the outcome, the score is a **lower** alphanumerical value than oil only.
2. If using a response action is likely to ***worsen*** the outcome, the score is a **higher** alphanumerical value than oil only.

The aim of this characterization is to methodically identify optimal response actions, as well as opportunities for risk managers (i.e., USCG FOSCs) to modify response actions that could then improve the outcome. Stated another way, through this assessment the USCG could modify response actions to change a yellow level of concern to a green, and a red level of concern to a yellow or green.

Key properties summarized by NOAA for the two oils used in the scenarios are presented in Tables 5.1 and 5.2. The specific composition of these crude oils can vary when produced and transported. The example MSDS used for these oils were provided by a participant from ExxonMobil Biomedical Sciences, Inc.

5.1 Bakken Oil Properties

Bakken crude oil is a light crude oil with an API of 36 to 44. It has a low viscosity and will float on the water surface. It will quickly spread into thin slicks, with significant amounts of the lighter fractions lost via evaporation (which can result in serious explosion/fire and inhalation risks). Bakken crude contains moderate concentrations of toxic (soluble) compounds, thus can pose risks to aquatic resources. In addition, it will oil and penetrate into intertidal habitats, causing the potential for fouling of riverine habitats and long-term contamination of sediments.

Bakken Sweet Crude Oil
Light crude oil - API of 36 to 44
Low viscosity and will float on the water surface.
Quickly spreads into thin slicks on the water surface.
Significant amounts of the lighter fractions lost via evaporation; may result in explosion/fire and inhalation risks.
Contains moderate concentrations of toxic (soluble) compounds, may pose risks to aquatic resources.
May coat and penetrate into intertidal habitats, with potential fouling of riverine habitats and sediments.
Low viscosity and will float on the water surface.
Density (at 15 °C): 0.813
Viscosity: 2.18 cSt at 40 degrees C
Pour Point: -73°C (-99°F) - 48°C (118°F)

Table 5.1 Properties of Bakken Crude Oil

5.2 Dilbit Oil Properties

Diluted bitumen, or dilbit, is bitumen—a heavy oil that has been blended with, one or more, lighter petroleum products, such as condensate (the oil co-produced from a gas well) or a naphtha-based oil. Once released, dilbit will initially behave as a medium crude oil. However, it will rapidly lose the volatile fraction of the diluent through evaporation, leaving behind the viscous bitumen. The diluents have high percentages of toxic, water-soluble components, resulting in greater risks to water-column organisms compared to heavier oils. Acutely toxic impacts from the diluent could be relatively severe, but limited to a localized area. Depending on the density of the bitumen, the residue may float or sink; depending on the viscosity, pour point, and ambient temperatures, the oil will spread into slicks or congeal into tarballs and tarmats; depending on what the bitumen was blended with, dilbit oil can change properties over time. SCAT and Operations teams should be asked to observe and report any buried oil or sinking.

Diluted Bitumen = Dilbit (Kearl)
Bitumen blended with a diluent - one or more light petroleum products, such as condensate or a naphtha-based oil.
Once released, initially behaves as a medium crude oil.
Rapidly loses volatile fraction of diluent through evaporation, leaving behind the viscous bitumen, which behaves as a heavy crude oil that is persistent in the environment.
Diluents - high percentages of toxic, water-soluble components; greater risks to water-column organisms compared to heavier oils.
Acutely toxic impacts from the diluent could be relatively severe, but limited to a localized area.
Depending on the density of the bitumen, residue (after loss of light ends) may float or sink (smothering hazards) and be sticky and difficult to recover.
Depending on the viscosity, pour point, and ambient temperatures, oil may spread into slicks or congeal into tarballs and tarmats.

Diluted Bitumen = Dilbit (Kearl)
Depending on the blends, the residue may change properties over time; e.g., could become non-floating if sediments are present in the water, submerge, and rest on the benthos and/or be buried in sediments.
Density: 0.94
Viscosity: 83 cSt at 40 degrees C
Pour Point: <(33) degrees F (for whole crude oil, i.e., both bitumen and diluent)

Table 5.2 Properties of dilbit oil

Additional information provided by NOAA oil database, ADIOS 2, and spill experience[13], provided the participants with further knowledge on weathering of dilbit oil. In general, recent studies have determined that the dilbit components will weather (components can be found in surface, mid-water, or bottom waters) within the first 72 to 96 hours, and the lighter, more toxic diluent components (the lighter ends) fractions of the oil will undergo weathering through evaporation. The specific gravity of residual heavier components will begin to approach 1.0 and, especially in freshwater and/or waters with particulate matter, be more likely to sink. Consequently, the risks of the options to manage the spilled oil risks were assessed twice, for each of two phases of oil behavior:

- Initial spill of oil: initial 2-6 hours and potentially up through 2 days, which is the approximate duration when public safety actions would take precedence over pollution response actions, i.e., the flammability risks for both oils should have diminished. NOTE: Additional weathering of the oils will continue until the lighter components are removed; about 72 to 96 hours, perhaps longer depending upon the actual oil and ambient conditions, a large majority of the lighter components are expected to evaporate into the atmosphere (Bakken and dilbit) or mix into the upper water column (Bakken).
- Weathered oil: through the initial 7-8 days, i.e., the approximate time after the emergency phase during which oil could still be found on the water surface and recoverable using traditional pollution response techniques. Sometime during the latter end of this timeframe, the residual bitumen component of dilbit oil would likely begin to pick up sediment in the water column and sink below the water surface, either in the water column or settle on the bottom.

Participants noted that R&D is needed to improve the ability to find and recover submerged dilbit oil, which is persistent, without damaging to the habitats and organisms, especially those that have a long period of recovery, such as the freshwater mussels and T/E or rare species. R&D that is in progress may also provide insights about reducing its persistence in the environment. Interaction with other particles in the water column will likely result in oil particle aggregates (OPAs), which could cause the formation of droplets. There are two types of OPA droplets and

[13] The NOAA ADIOS database includes estimates of the physical properties of dilbit oils and products. Using this information, NOAA has incorporated a dilbit oil into the ADIOS 2 to predict *changes* in those properties once the oil has been released. The properties evaluated for dilbit oil include the density, viscosity, and water content of the product; as well as the rates at which it evaporates from the sea surface, disperses into the water column, and forms oil droplets that become emulsified, suspended, or sinks in the water.

they will either sink or rise to the surface. One has more sediment than oil; the other has more oil than sediments. Adhesion (stickiness) of the oil is an important characteristic. In the Delaware Bay, we expect more adhesion of oil to the sediments and particles in the Bay. If the oil readily forms droplets, this could reduce the potential for smothering by submerged oil mats and increase the rate of biodegradation of the oil.

Shared assumptions and observations identified by the participants include:

- The risk assessment matrices *generally* omit physical-contact oil detection methods because these methods would not be needed for Bakken oil, nor would they likely be implemented in the first seven days of a dilbit oil spill. While these response actions could be appropriate and potentially useful for dilbit oil spills, they would be implemented after the diluent components separated from the bitumen crude oil.
- Handling of waste is a potential pathway and that waste management will be correctly carried out; therefore, this risk is only a concern if waste BMPs are not followed. It is assumed that waste will drop out as a risk, but participants agreed they cannot disregard waste because there are cleanup options such as skimming with the possibility of approved decanting, and recanting, which could add contaminants back into the environment.
- The focus on the ERA was on wetlands, e.g., marshes that could be exposed to spilled or floating oil, rather than uplands. The three states value marsh grass species differently, e.g., NJ considers *Phragmites australis* worthy of protection while the other states consider it less important.
- Participants recognized that some areas considered upland (dry area) are within the scenario scope yet participants did not use a common definition of upland. Some places may be 10 miles from a water body but not considered upland (dry area).

5.3 Health and Safety Risk Characterization

The use of foam in on the spilled oil to suppress vapors and potentially extinguish fires was discussed by all workgroups. Three types of foam are stockpiled on facilities in the region: PKW, Thunderstorm FC-601A, and UNIVERSAL GOLD 1% / 3%. After reviewing their respective MSDSs, participants reached several conclusions:

1. In an urban environment, public safety concerns could require fire fighters to continuously apply foam to suppress vapors and prevent fires near people.
2. When spilled onto coastal waters, foam would not be a preferred pollution response action due to the potential for adverse impacts on marine and estuarine organisms and habitats and the inability to maintain a foam barrier between the spilled oil and the atmosphere.
3. Logistically, applying foam from industry stockpiles is a challenge if needed outside of the facility where it is stored.
4. Since public safety concerns could drive the application of foam regardless of concerns about ecological risks, and to more fully inform decision-making, participants identified the need to have further study of the potential water column concentrations and toxicity of foam if applied in coastal (marine, estuarine) waters.

Human health risks from flammable vapors and fires were also characterized by the workgroups for both oil types. The workgroups considered risks to both workers (first responders and pollution responders) and the general public. CTEH proposed groups of health-related socio-economic resources (workers, sensitive receptors (e.g., children, elderly, and sick), and potential communities in proximity to the incident) and drafted the initial conceptual model for human health and safety (HHS) using Scenario 1, because this spill location occurs in a densely populated, urban area. Figure 5.1 displays the characterization of Scenario 1 HHS risks, which are predominantly associated with flammability and benzene hazards when the oil is first spilled. There would be a slightly elevated risk to humans from just monitoring the vapors, but risk is still considered low and is denoted as a limited level of concern (green) due to the outdoor, transient nature of the flammability and inhalational exposures. If no fire occurred, implementing various response actions would present a lower risk to HHS than the fire, although these actions could result in slight risks, e.g., from vapors, to workers and people in the transportation community who could not shelter in place.

Participants characterized risks of monitoring only as resulting in some potential impairment to, with rapid recovery by, sensitive receptors (i.e., the sick, elderly, and children), nearby transportation and residential communities and as being overall, a low concern. If a fire occurred and response actions were to either let the oil burn or add extinguishing agents, the potential for impairment to human/socio-economic resources would increase over the risk of the oil alone; recovery from fire and foam/water damage or injury could take 1 to 4 years. Impacts could potentially arise from dermal exposure, and inhalational exposure to combustion byproducts of oil including PAHs and fire smoke, as well as the fire-fighting foam itself. Participants raised several questions about the use of foam but lacked the necessary information to resolve them.

Habitat	Human Health and Safety					
Sub habitats	Work Area (e.g., hot and warm zones), plus Public Health (Transportation, Industrial, Residential/Recreational Communities)					
Oil Type	B1	B1	B1	B1	B1	B1
Resources of concern (Socio-economic)	Workers	Residential Community	Sensitive Receptors	Commercial Community	Industrial Community	Transportation Community
Human health and safety receptors relevant to this ERA	First Responders (on water/on land), safety monitoring, oil recovery operations (on water/on land), oil contamination monitoring/SCAT	All - adults, adolescents; also children, elderly, sick (personal residences)	Children, Elderly, Sick (daycares, hospitals, nursing homes)	Adults (shops, general commercial facilities)	Adults (nearby refineries, plants, etc.)	Mostly Adults (rail, marine, roads: drivers, passengers)

Figure 5.1 Risk Characterization: Human Health/Socio-economic Resources of Concern

The summaries of the workgroups' risk characterizations of the different response actions, in relation to the risk of oil only, associated with each of the five scenarios are discussed in the following sections. Detailed notes, including assumptions made by workgroup participants, were taken by recorders in each of the workgroups and were used to develop the discussion below.

5.4 Scenario 1 – Bakken Rail Incident, Philadelphia

Scenario 1 addressed an urban rail incident involving Bakken crude oil in the same location as an actual derailment that occurred January 20, 2014 (Figure 5.2). [NOTE: The incident occurred at the Arsenal Bridge located in the University City neighborhood of Philadelphia, PA on January 15, 2015, and resulted in damage to four railcars but no spillage of oil.] For this scenario, approximately 100,000 gallons of Bakken cargo released, half of which entered the Schuylkill River. The other half of the discharge spilled on land and caught fire in a highly-populated urban area near commercial and residential areas, sports centers, nursing homes, schools, and water intakes. At this time of year, ice is often present on the river, with snow onshore.

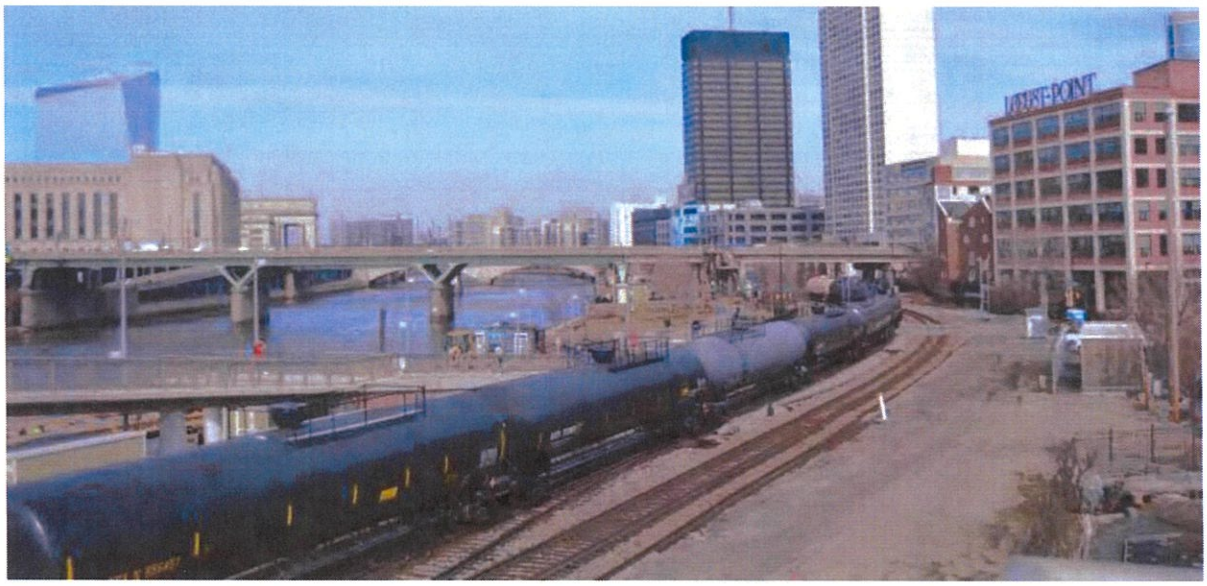

Figure 5.2 Crude oil by rail at the Arsenal Bridge in Philadelphia

(Photo Credit -http://planphilly.com/articles/2014/03/13/csx-testifies-on-derailment-25th-street-bridge)

For this scenario, Philadelphia Office of Emergency Management ran the Interagency Modeling and Atmospheric Assessment Center (IMAAC) plume model. Figure 5.3 shows the conditions and result of the model.

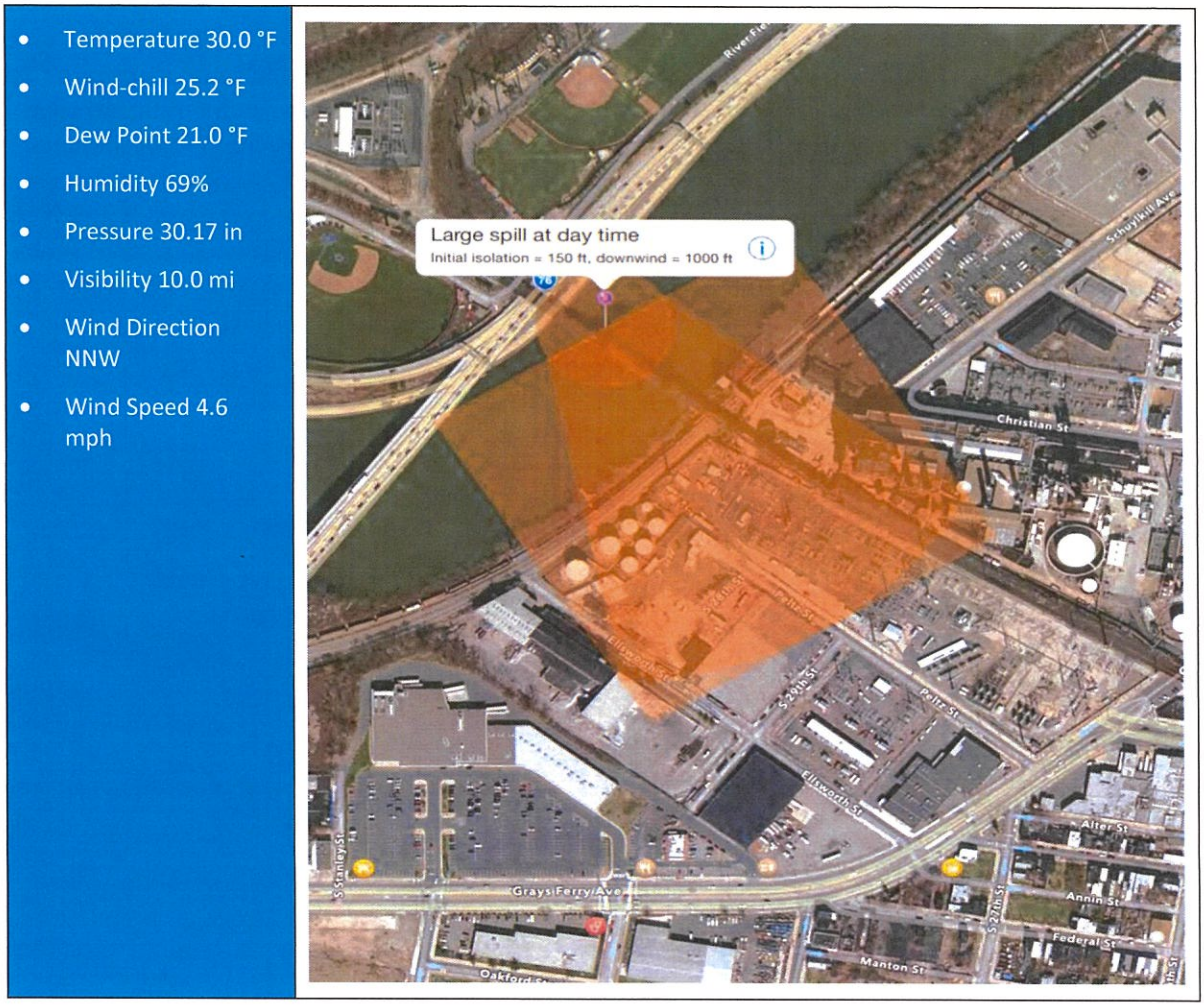

Figure 5.3 Smoke Plume model for Scenario 1

Participants reviewed the information contained in Appendix H:

- The weathering of the oil over time, in terms of amount that would evaporate and remain in the environment (shown in the oil budget table), and benzene concentrations, was calculated by NOAA's ADIOS 2.
- The oil spread predictions from trajectory model, including possible extent of contamination over 4 days, in relation to the ESI maps for the area.

The ADIOS 2 program shows that of the 50,000 gals of Bakken oil that did not burn, the oil that spilled into the Schuylkill River and on the adjacent shore would rapidly evaporate. ADIOS 2 estimated that the oil would move about 1.5 nautical mile (nm) in total within the Schuylkill River (0.7 nm upstream and 0.8 nm downstream) and provided an oil budget for the 50,000 gals that did not burn in this scenario (Table 5.3).

Time/Fate	*Floating*	*Beached*	*Evaporated/Dispersed*
After 24 Hours	9,400 gallons (18.8%)	23,000 gallons (46%)	17,600 (35.2%)
After 48 Hours	5,750 gallons (11.5%)	17,500 gallons (35%)	26,750 (53.5%)
After 72 Hours	3,900 gallons (7.8%)	14,350 gallons (28.7%)	31,750 (63.5%)
After 96 Hours	3,050 gallons (6.1%)	11,900 gallons (23.8%)	35,050 (70.1%)

Table 5.3 Oil budget for Scenario 1

The primary driver for the highest level of concern (red) is the potential presence of peregrine falcons, bald eagles, and osprey, which could be feeding (fishing) in the area of contamination. If a bald eagle or osprey was exposed to the oil, and was part of a mating pair, there would be a significant potential impact for a relatively long period of time.

Phase 1 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 1 (initial 6 hours) associated with no action other than monitoring plus all response actions for this scenario are shown in Figure 5.4.

As noted above, the driver for the highest level of concern was the potential presence of peregrine falcons, osprey, and bald eagles, which could be adversely impacted by the physical event, the oil, and the response activities taking place. The use of foam was also a concern on macro-invertebrates, such as freshwater mussels. Due to these concerns, the summary risk in intertidal shoreline with the use of foam was red.

Participants were also concerned about the use of foam to macroinvertebrates in waters 0-2 meters deep, as well as fishery closures. While a fishery might be closed to reduce the risk of oil tainting, closing the fishery would not necessarily reduce the risk from exposure to fire-fighting foam.

Participants had moderate level of concern regarding the potential impact of oil recovery and removal activities where oil stranded in the intertidal zone and surface waters where aquatic vegetation might be present. N/A was applied when the resources of concern listed in the matrix were not present in this scenario area.

Except for the flammability and foam concerns, a low level of concern was expressed about potential risk to other ecological resources of concern during the early hours of the incident.

Phase 2 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 2 (initial 7 days) associated with no action other than monitoring plus all response actions for this scenario are shown in Figure 5.5.

Given the rapid weathering of Bakken oil, January spill time, and the urbanized setting, the risks were characterized as the same as Phase 1.

Figure 5.5 Scenario 1 Risk Characterization (Phase 2)

5.5 Scenario 2 – Bakken Barge Incident, Delaware River

Scenario 2 was an incident involving a barge carrying Bakken crude oil. The 50,000-gallon spill occurred on the Delaware River at Eddystone, PA on April 15, 2015, an ecologically-sensitive time of year. The released cargo impacts Pea Patch Island, the largest heron rookery on the East Coast of the United States north of Florida.

Figure 5.6 shows one of the articulated tug and barges used to transport Bakken oil in the Delaware Bay.

Figure 5.6 US Ship Co. barge, ***Petrochem Producer****, used to transport Bakken oil.*

(Photo credit: Delaware Bay and River Cooperative)

Participants reviewed the information contained in Appendix H:

- The weathering of the oil over time, in terms of amount that would evaporate and remain in the environment (shown in the oil budget table), and benzene concentrations, were calculated by the ADIOS 2 program.
- The oil spread predictions from the trajectory model, including possible extent of contamination over four days, in relation to the ESI maps for the area.

Phase 1 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 1 (initial 6 hours) associated with no action other than monitoring plus all response actions for this scenario are presented in Figure 5.7.

Participants made the assumption that 25,000 gals floated on the river, that shorelines would be pre-cleaned to prevent the oiling of debris, and that there would be some oiling on adjacent shorelines, mostly in New Jersey. The oil spread on the river initially ranged from Wilmington, DE south of the C&D Canal to the Augustine Wildlife Area in Delaware. Fire was not part of this scenario and response actions for fire were NA but vapor hazards were a risk and considered.

Artificial and natural shorelines were assumed to be above the mean high tide mark and thus not oiled.

Shoreline cleanup of Bakken oil residue was not considered likely in intertidal shorelines during Phase 1, or in the water column, so these were also ranked NA. Participants expressed a moderate level of concern with the potential exposure of mammals, birds, reptiles/amphibians, and T/E animals and plants to Bakken oil onshore and in the upper water column. At this time of year, people could be fishing and participants considered whether the smell of oil would be a voluntary disincentive to stop fishing. Advisories would likely be issued but not shut down. Participants agreed that if people could smell oil, they could be exposed and should take precautionary efforts, and also recognized that state and local health departments would make public health determinations and issue advisories.

Participants assumed that vapor issues from Bakken to mammals and birds would impair them but should recover in less than one year. Amphibians receive higher risk rankings because both inhalation and absorption is higher through the skin.

Compared to oil only, implementing measures to control the spread of oil where T/E animals might be present in the intertidal zone decreased the risk from moderate to low; but this action also increased slightly the risk to T/E plants if they were in the pathway of the spilled oil. T/E plants in artificial shoreline received a 4D ranking because participants did not believe there were any in the area.

Phase 2 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 2 (initial 7 days) associated with no action other than monitoring plus all response actions for this scenario are presented in Figure 5.8.

In the Phase 2 timeframe, floating oil could be found in areas farther north from Trainer, PA and Logan Township, NJ but no further south than the Augustine Wildlife Area in Delaware.

Compared to the oil only, changes in potential risk were few and primarily related to the potential impact of shoreline cleanup activities to remove stranded oil, which would likely be light, e.g., bathtub ring. Shoreline cleanup in intertidal areas where T/E animals, e.g., osprey and bald eagles (recovered T/E species) might be present or hazed into oiled areas, was scored a high level of concern (red), and the level of concern increased from low (green) to moderate (yellow) for reptiles/amphibians that could be present on artificial and natural terrestrial shorelines. Potential risk also increased to moderate level of concern about the impact of shoreline cleanup activities in the intertidal zone on mammals, birds, reptiles/amphibians, and plants.

Habitat	Artificial Shorelines							Natural Terrestrial Shorelines							Intertidal Shoreline (Exposed & Sheltered) / Surface Water (0 - 1 meter)									Mid-water (0 to 2 meters)									Benthic (bottom, >2 meters)

Figure 5.8 Scenario 2 Risk Characterization (Phase 2)

One potential gap in the assessment was a Section 106 consultation under the NHPA, which requires a review of proposed actions (i.e., response actions) with interested parties, e.g., federally-recognized tribes (there are none in NJ), and weighing of project alternatives to avoid or minimize damage to significant historic and cultural properties. Some ESI maps captured some archaeological sites.

5.6 Scenario 3 – Bakken Tanker Incident, Delaware Bay

Scenario 3 was an incident involving a tanker carrying Bakken crude oil. The incident, a 500,000-gallon discharge, occurs in the middle of the northern end of Delaware Bay (saltwater) on January 15, 2015. The resultant spill involves highly flammable vapors that limits response and navigation within the reaches of the oil, and could have greater impacts on the ecologically-diverse shorelines of three states (Pennsylvania, Delaware, and New Jersey) if it occurred in the other seasons.

Participants reviewed the information contained in Appendix H:

- The weathering of the oil over time, in terms of amount that would evaporate and remain in the environment (shown in the oil budget table), and benzene concentrations, was calculated by the ADIOS 2 program.
- The oil trajectory predictions include the possible extent of contamination over the first four days, in relation to the ESI maps and resources of concern for the area.

Trajectory models for this scenario were run with two different winds because initial models run with no winds present allowed the tidal action to dominate the movement and spread of oil, which resulted in no shoreline impacts taking place. This was considered improbable by the participants, so a second trajectory model run was requested using seasonally-prevailing winds. The wind conditions are:

- 0 knots (essentially calm; only tides and currents affected the spread of the oil); no shoreline impacts were realized using this scenario, and
- 8-13 knots from the north/northwest (seasonally prevailing winds); resulted in likely shoreline impacts from the spilled oil.

Phase 1 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 1 (initial to 6 hours) associated with no action other than monitoring and other response actions for this scenario are presented in Figure 5.9.

The weathering and trajectory models showed that in the first six hours, with winds of 0 knots, the oil would spread but would remain in the vicinity of the tanker and be transported within the bay and river by tidal conditions and currents only; there were no shoreline impacts with this trajectory. With these conditions, the ADIOS 2 program estimates that 16% of the oil would evaporate, leaving 84% of the spilled Bakken oil on the water. For this reason, HHS concerns over the potential ignition of the flammable vapors was the primary driver to take no response action during Phase 1, other than to prevent a fire from starting. Participants discussed vapor suppression but determined that would not be an option as maintaining a foam vapor barrier would be impossible in open waters and the volumes of foam required were not present in the quantities needed. Additionally, responder operations would be limited by LEL thresholds. If

readings do not allow for safe working, responders would not go into the flammable zone and put personnel at greater risk.

They also noted that the vapor density would be heavier than air especially in calm winds; the flammable vapors could provide a health and safety hazard to responders as the vapors could potentially displace oxygen. Wind or rain would reduce/move vapor density. Participants requested additional research/studies conducted on the vapor density, particularly how high above the surface the vapors were likely to be present, and noted the need to carry LELs on the OSRVs.

Participants characterized the risks of oil only, since no other actions could be taken during Phase 1. For this reason, the majority of the chart is ranked NA. The water depth in this location is approximately 25 to 40 feet, and the first six hours would have some mid-water impacts with components of the oil dissolving in the upper 2 meters of the water column. The highest risk of concern would be for any T/E plants and animals on the shorelines, which might not be present due to seasonality, but was ranked red out of caution. Sturgeon has been present in the benthic zone in the past. Protective booming would be desirable. Moderate level of concern (yellow) was assigned for birds, reptiles/amphibians, macro invertebrates, and aquatic vegetation on sensitive wetlands and riprap shorelines and the upper water column that could be exposed to the spilled oil.

Phase 2 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 2 (4 to 7 days) associated with no action other than monitoring plus all response actions for this scenario are presented in Figure 5.10.

In addition to the risks identified during Phase 1, some additional risks were noted as being possible and applicable to specific resources of concern. Participants spent the majority of their discussion time considering Phase 2 with the higher wind conditions and treated this as a typical crude oil once the flammable light ends evaporate. Primarily in the intertidal shoreline, participants noted that some response actions could reduce the risks presented by the oil alone. Specifically, implementing diversion and exclusion booming response actions to protect sensitive shorelines from being oiled, shoreline cleanup response actions to remove oil residue from the shore, and implementing on water recovery / skimming when practicable, would slightly decrease risks to mammals, reptiles/amphibians, plants, and aquatic vegetation.

Since the time of the scenario was January, participants discussed the likelihood that sensitive shoreline habitats would be less impacted by the oil and that natural weathering and NAM might be the response action of lowest risk to the shoreline. However the large quantities of oil discharged, which could result in longer-term shoreline impacts, required consideration of additional response actions. If the scenario had been set in spring, the risks to ecological resources from the oil, and probably shoreline cleanup actions, would have been ranked higher.

Figure 5.10 Scenario 3 Risk Characterization (Phase 2)

5.7 Scenario 4 – Dilbit Rail Incident, Mantua Creek

Scenario Four was a railcar incident involving Dilbit crude oil. The bitumen in dilbit contains resins and asphaltenes, which makes it stickier than typical heavy crude. It is more likely to sink in freshwater than saltwater.

The incident occurred at the rail crossing over Mantua Creek in Paulsboro, New Jersey on May 25, 2015, in the vicinity of an actual train derailment in 2012 that released vinyl chloride (Figure 5.10). The Mantua Creek is freshwater and approximately 2 meters deep. Much of Mantua Creek's floodplain contains highly disturbed soils consistent with historical and current urban uses (Figure 5.11). Approximately 100,000 gallons of oil was released impacting freshwater marshes, the Mantua Creek and parts of the Delaware River.

Figure 5.11 Train derailment in Paulsboro, NJ, 2012

(Source: http://wac.450f.edgecastcdn.net/80450F/nj1015.com/files/2012/12/crane3-300x224.jpg)

Participants reviewed the information contained in Appendix H:

- The weathering of the oil over time, in terms of amount that would evaporate and remain in the environment (shown in the oil budget table), and benzene concentrations, was calculated by the ADIOS 2 program.
- The oil spread predictions from trajectory model, including possible extent of contamination over 3 days, in relation to the ESI maps for the area.

Workgroup participants identified the need to involve the SHPO and HPA, as well as natural resource agencies to fill data gaps with regard to estimates of fish and bird populations in the area, which increased uncertainty around severity estimates.

Phase 1 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 1 (initial 6 hours) associated response actions for this scenario are presented in Figure 5.12.

The trajectory model predicted that dilbit oil spilled just after peak high tide (at 0741) would move from the creek into the Delaware River during the first six hours. The ADIOS 2 program estimated that 20% of this oil would evaporate in the first six hours, leaving approximately 80% of the oil in the environment. There were response organizations nearby and could begin pollution response operations quickly but probably not in time to implement containment booming and skimming to prevent the majority of the oil from moving into the Delaware River.

Mantua Creek has been historically impacted by point-source and non-point source pollution, including oil spills, releases of hazardous wastes, sewage, and run off. Upstream there are wetland areas, with freshwater streams to the north and south; a narrow channel opens to a freshwater marsh with salamanders and turtles. A primary driver of ecological risk is oil exposure and trampling/crushing by responders or vehicles. Of particular concern are turtles, which have inherently very low infant survival rates coupled with low adult reproductive rates.

The incident location is near the Paulsboro community. If a fire occurred from the incident, it would create air hazard risks for the community. While applying foam was not viewed as logistically feasible in this situation, participants would like to know more about the composition of these foams and their potential environmental interactions.

Participants assumed that animals in the water would not exit the water, and land animals would flee the area for any kind of active response and so the risk of impact would be low from fire. T/E species were ranked NA since there are no documented occurrence in the area during winter, nor was there suitable habitat present. .

The overall assessment of risks during this phase are low (green) to moderate (yellow). Participants assigned a moderate level of concern for oil only for mammals, birds, reptiles/amphibians and macro-invertebrates (freshwater mussels) on shorelines, plus marsh vegetation, in the surface/midwater habitat. Fire could reduce the risk to green for mammals and birds, and marshes by removing the source of oil contamination. In the case of no fire, implementing oil spread control, on water protection (booming) and recovery response actions could also slightly reduce the risk to the same resources of concern. With the industry resources located nearby, participants assumed a barge could be deployed quickly as temporary storage of oil and some oily water recovered by skimmers. Participants, however, were uncertain about temporary storage of large quantities of recovered oily water; if this were not quickly solvable (e.g., by decanting) then skimming operations might be curtailed.

Phase 2 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 2 (4 to 7 days) associated with no action other than monitoring plus all response actions for this scenario are presented in Figure 5.13.

In this scenario, it was assumed that the worst case scenario would be that the Dilbit would sink, and likely severely impact (smother) benthic organisms and their habitat. The extent of contamination would begin in Mantua Creek, move into the Delaware River in the first tidal cycle. It was also assumed, as worst case scenario that most, if not all, sunken oil would remain in the Mantua Creek sediments or likely go virtually undetected in the Delaware River. The trajectory model of floating oil movement, therefore, was limited to 3 days, and floating oil would be minimized by boom deployment at Mantua Creek-Delaware River confluence.

Unable to Determine Due to Insufficient Information

Figure 5.13 Scenario 4 Risk Characterization (Phase 2)

Workgroup participants assumed that during Phase 2, the weathered oil would sink to the bottom of Mantua Creek, and in the Delaware River. Smothering impacts caused the risk of oil only to change to red for certain resources of concern, i.e., reptiles/amphibians, macro-invertebrates (freshwater mussel beds), and aquatic plants. Participants noted that there are freshwater mussel beds in New Jersey that did not appear on the ESI maps. Also, more information is needed to assess the potential benefits and limitations of the response actions. For example, if the bottom of the creek is essentially paved with this oil, is it better to cap the creek bottom, dredge and possibly re-release existing contaminants, or leave the contaminants in place given the potential for toxic components to leach into the benthic habitat. If sediments or other materials were added to cover the oil, would that be considered filling a wetland, which could trigger other federal and/or state regulatory requirements that may need to be considered in the response action? The ranking of red does not mean to stop actions, but rather to view and assure that response actions would not adversely affect the species of concern.

5.8 Scenario 5 – Dilbit Barge Incident, Delaware River

Scenario Five was a barge incident involving Dilbit crude oil. The incident occurred at the Marcus Hook Anchorage in Pennsylvania on April 15, 2015 in brackish water. Predicting how dilbit would behave in the brackish to salt water of the lower Delaware River is unclear. The "salt line"[14] in the Delaware River is generally around the Delaware Memorial Bridge south of Wilmington, DE, and the river north of the salt line is brackish. Approximately 50,000 gallons of cargo is spilled into the Delaware River south of the Delaware Memorial Bridge, ultimately impacting the ecologically diverse shorelines of three states (Pennsylvania, Delaware, and New Jersey).

Participants reviewed the information contained in Appendix H:

- The weathering of the oil over time, in terms of amount that would evaporate and remain in the environment (shown in the oil budget table), and benzene concentrations, was calculated by ADIOS 2.
- The oil spread predictions from trajectory model, including possible extent of contamination over 4 days, in relation to the ESI maps for the area.

The recent spill experiences, FOSC report, and the Delaware River and Bay Oil Spill Advisory Committee Report (DRBOSAC) report, which was mandated by Congress, about the *M/T Athos* spill (Nov. 24, 2004) of 265,000 gals of Venezuelan heavy crude oil, and the *T/V Presidente Rivera* (June 24, 1989) 306,000 gal of No. 6 fuel oil, was used to inform assessing the risks associated with this scenario of floating/submerged crudes. In both of these spill incidents the heavy crude acquired suspended sediments as it weathered and went from a floating to sinking submerged oil.

Participants assumed that no fire would occur in this scenario; therefore, they assigned NA to all fire-related response actions. They also assumed for purposes of the assessment, that 75% of the oil would be on the surface for spreading and recovery; and that 25% would become sunken.

[14] Salt-laced water, known in water jargon as the "salt front" or "salt line," is 250 milligram per liter chloride concentration. This concentration is based on drinking water quality standards originally established by the U.S. Public Health Service. Source: http://www.state.nj.us/drbc/hydrological/river/salt/

Phase 1 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 1 (2-6 hours) associated with no action other than monitoring and other response actions for this scenario are presented in Figure 5.14.

ADIOS 2 estimated that 23% of this oil would evaporate in the first six hours, leaving approximately 77% of the oil in the environment. In this scenario, vapor control was not considered a significant risk.

Source control and protecting the creeks from floating oil was the priority response actions.

Participants scored the risks from the oil and monitoring as low (green) for the resources of concern in artificial and natural terrestrial shoreline, with the exception of moderate concern for reptiles/amphibians on artificial shorelines. Participants assigned a high level of concern (red) for birds, reptiles/amphibians, macro-invertebrates, T/E animals and plants, and plants associated with the oiling of intertidal areas, and for birds in the surface/mid water column. Participants were moderately concerned (yellow) about potential risks in the water column to reptiles (turtles), aquatic vegetation, macro-invertebrates, T/E animals (Atlantic sturgeon), as well as for species that are fished and water intakes.

Compared to oil only, participants noted that some pollution response actions could mitigate risks from the spilled oil, i.e., containment booming (oil spread control) and skimming (on water oil recovery), and protective booming for mammals in the intertidal area. These actions could also be beneficial if their implementation resulted in reducing the oil threat to benthic resources of concern.

At this time of the year, early spring, many species of invertebrates and vertebrates are breeding producing large numbers of pelagic/nektonic larva. Some of these are meroplankton floating near the surface, while others like the striped bass eggs tumble alone the bottom driven by tidal currents. In both of these circumstances, potential adverse oiling impacts would be high.

Phase 2 – Risk Characterization

The detailed results of the participants' characterization of risks during Phase 2 (4-7 days) associated with no action other than monitoring plus all response actions for this scenario are presented in Figure 5.15.

After 3-4 days, 73% of the spilled dilbit crude, would remain in the environment as a heavy thick crude. Depending upon the actual blend, the specific gravity of the residual oil could hover around or above 1.0, which is the specific gravity for freshwater at 4°C.[15] . This rapid loss of the light diluent as a result of evaporation and weathering is important to consider. After the rapid evaporation/weathering, the resultant heavy thick crude has more resins and asphaltenes and is more sticky and tackier than typical heavy crudes. The increased 'stickiness' increases the probability of having suspended sediments attach to the oil droplets, thus increasing its specific gravity, making it heaver in the water and sink below the surface. Participants anticipated considerable shoreline contamination of heavy oil with this scenario, and that the oil would begin to pick up sediment in the water and begin to sink.

[15] Oils with a specific gravity of less than 1.0 will float on the water surface; those greater than 1.0 will not float.

Figure 5.15 Scenario 5 Risk Characterization (Phase 2)

The Delaware estuary turbidity maximum (ETM) falls (in general) between the vicinity of Marcus Hook (RM 79) in the north and a line between the Cohansey River in New Jersey and the Smyrna River (RM 44) in Delaware. This ETM zone is characterized by the increase in salinity from a freshwater condition (0-0.5 ppt) to that of an oligohaline concentration (0.5-5 ppt) moving down river to the Smyrna River area. These high sediment concentrations are caused primarily by the resuspension of fine-grained sediments by strong tidal currents in this region and the formation of additional sediments as dissolved organic matter from land runoff interacts with diluted salt water to form larger particles. The Delaware Estuary is widely recognized as being one of the most turbid, sediment-laden estuaries in the United States. In this environment, when dilbit separates from its blended light/heavy composite it forms into the thick heavy sticky crude, and adhesion of sediment particulates onto the crude droplets will cause the crude to submerge creating a challenging tracking and recovery operation.

Shoreline oiling could occur on both sides of the Delaware River north to about the Schuylkill River on the PA side and south of the C&D Canal to around Augustine Creek in Delaware and Alloway Creek in New Jersey. Participants would have preferred to have more detailed information about the degree of oiling on specific shoreline types. Using available information as well as their prior response experience, they completed the risk characterization for this scenario.

Compared to Phase 1, participants had a higher level of concern (red) about this phase of oiling for resources of concern (aquatic vegetation, macroinvertebrates, aquatic invertebrates, and T/E animals) associated with the benthic sub-habitat. In fact, the summary of risk was scored high (red) for both oil alone and pollution response actions for resources of concern in three habitats: intertidal shorelines, surface/mid-water column, and benthos. Participants identified some pollution response actions that could reduce the risk to certain resources of concern from moderate (yellow) to low (green): oil spread control through containment booming (could reduce risk to mammals, e.g., river otter, muskrat, raccoon, in the intertidal shorelines; aquatic vegetation, macro-invertebrates, and aquatic invertebrates in the bottom of the water column), and on-water oil recovery (could reduce risk to mammals, e.g., river otter, and macro-invertebrates at the water surface). On the other hand, shoreline cleanup would increase the risks to reptiles/amphibians and macro-invertebrates on artificial shorelines from moderate (yellow) to high (red).

Appendix B: Workshops Agendas

USCG Sector Delaware Bay Consensus Ecological Risk Assessment Meeting

Workshop 1 – Agenda

Delaware County Emergency Training Center
1600 Calcon Hook Rd, Sharon Hill, PA 19079; Phone (610) 237-8630
Workshop 1 - Day 1

June 9, 2015

All refreshments graciously sponsored by industry members Of the Delaware Bay and River Cooperative

0730

Registration/check in + coffee and tea

0800

Welcome and Opening Comments (CAPT Benjamin Cooper, Commanding Officer, Sector Delaware Bay and Federal On-scene Coordinator

0815

Introductions (Ann Hayward Walker, SEA Consulting Group)

Project Committee and Subcommittees
Workshop participants

0830

Background – Sector DelBay Project (LCDR Michael Weaver and LT Eric Nielsen)

Sector Delaware Bay Project
- Project Objectives and scope (LCDR Weaver)
  - Anticipated use, and value, of project results
  - Planning only – results are not binding during response
  - Scope: Bakken and Dilbit crude oil transported by rail (crossing over streams/rivers) and barge (coast and in Delaware Bay)

Overview of Rail Incidents in the AOR
- Scenario locations (LT Nielsen)

0915

ERA Background (SEA)

- Opportunities and limitations of ERAs
- What are the objectives of this workshop?

0930

Introduction to Consensus Ecological Risk Assessments (SEA)

Using the Coast Guard Assessment Guidebook

- Previous Workshops
- What consensus means + value of consensus to

project results Essential activities of the process

- *Activities 1-5: Conducted by Project Committee and Subcommittees; presentations given at this workshop*
- *Activities 6-8: Conduct at this workshop*
- *Activities 8-10: Continue at next workshop*
- *Activities 11-12: Post-workshops, final report and implementation of findings*

1000

Break (20 mins.)

1020

Pre-workshop Planning (SEA)

Continue with Subcommittee Pre-Workshop Activities - Presentations by subcommittee leads

1020

Subcommittee Pre-Workshop Activities - Transport Subcommittee Lead – Ed Levine

- EPA response to incidents and OHMSETT study – Mike Towle, EPA
- Human/public health considerations – Kelly Scribner, BTEH
- Behavior and Transport - Ed Levine, NOAA
    - Oil behavior
    - Oil transport for the 4 water scenarios: NOAA oil trajectory and behavior – distribution of oil: air/water surface/water subsurface
    - For the Bakken/urban/fire scenario: Interagency Modeling and Atmospheric Assessment Center (IMAAC) smoke plume model output, courtesy Philadelphia OEM

1230

LUNCH (1 Hour) – provided

1330

Resources Subcommittee – Ben Anderson, DNREC and Debra Scholz, SEA

- Definition/description of ecological and socio-economic resources of concern in study area
- Information, data sources and references

1415

Pre-Workshop Activities - Effects Subcommittee – Clay Stern, USFWS

- Defining effects
  - General objectives of the analysis phase
  - Using fate and effect information
- Using thresholds to estimate the sensitivity to oil of the resources at risk
  - Exposure
  - Sensitivity
  - Effect
- Suggest thresholds measures for use in the analysis for specific resources
- Data collection concerning hazards relative to endpoints and resources identified in the conceptual model
- Information, data sources and references

1530

BREAK (15 Mins)

1545

Continue with Response Operations Subcommittee Pre-Workshop Activities - Rich Gaudiosi, Delaware Bay and River Cooperative (DelBay Co-op)

- Description of each response option
- Resources required (logistics) to implement the option
- Operational limitations
- Anticipated efficiency of each option (single %; or % of the upper and lower range, or other %?)
- Implications of using the option on oil fate
- Concerns associated with using the option
- Information, data sources and references (used to date and sources for risk analysis and characterization – next workshop)

1700

Review the results of the first day (SEA) Introduction to tomorrow (SEA) Questions/discussion (all)

1715

ADJOURN

Workshop 1 - Day 2

June 10, 2015

0800

Review the results of the first day
(SEA) Review process for today

- Conceptual model
- Conducting the analysis for natural attenuation and monitoring (NAM)
- Using the Risk Ranking Matrix
- Workgroups will determine the risk – 2 groups for each scenario, then meet and reach consensus
- Estimating levels of concern - simplifying the scores
- Achieving consensus on final risk scores
- Evaluating the relative risk for the response options under consideration
- How can you compare effects – the NAM baseline
- Preparing the relative risk summary

0815

Industry presentation on new safety course for moving crude by rail – Suzanne Lemieux, API

0830

Foam, Logistics and Port Asset for Fire & Spill Response - Chief Jim Kelly, Sunoco Logistics

0845

Review of the Conceptual Model – SEA

0915

Determining the level of concern – Clay Stern, USFWS

- Risk matrix concept
- Developing a matrix scale

0945

Expert Presentation on Fate of Dilbit Oil in the Environment – Michel Boufadel, NJIT

1015

BREAK (30 mins.)

1045

Establishing the Baseline for Effects: Natural Attenuation and Monitoring (NAM) – Clay Stern, USFWS

1100

Begin Preliminary Risk Scoring – Workgroups for each of the five scenarios

Participants assigned to workgroups (2 workgroups/scenario) and breakout rooms

1145

Time Out - Review and compare initial scores

1230

Lunch (provided)

1330

Continue preliminary risk scoring for baseline (break refreshments at 1445)

1520

Review, discussion and revision of baseline (NAM) scores

1600

Next workshop - Assignments (Preparation required! Homework to gather data/information about resources of concern to characterize effects of response options in the next workshop)

1615

Questions to be addressed before the next workshop (June 23-24, 2015 – same location and hours)

1630

ADJOURN

USCG Sector Delaware Bay Consensus Ecological Risk Assessment Meeting

Workshop 2 - Agenda

Delaware County Emergency Training Center
1600 Calcon Hook Rd, Sharon Hill, PA 19079; Phone (610) 237-8630

Workshop 2 - Day 1
June 23, 2015

Refreshments graciously sponsored by the Delaware Bay and River Cooperative members

0730

Registration/check in + coffee and tea

0800

Welcome and Opening Comments

0815

Introductions (Ann Hayward Walker, SEA Consulting Group)

Project Committee and Subcommittees
Workshop participants

0830

Process Overview (Walker)

- Adapting the Coast Guard Assessment Guidebook for this ERA
  - What consensus means + value of consensus to project results
- Essential activities of the process
  - *Activities 1-5: Conducted by Project Committee and Subcommittees; presentations given at Workshop 1*
  - *Activities 6-8: Workshop 1*
  - *Activities 8-10: Workshop 2*
  - *Activities 11-12: Post-workshops, final report and implementation of findings*

0915

Workshop 2 Overview (SEA)

- Objectives of Workshop 2
- Review of agenda and activities
- Assess response actions for two timeframes o Initial 2-4 hours after incident begins o 4-7 days after incident begins

0945

Rail Company Presentation(s)

Spill response planning, resources/capabilities, and railroad local training options to manage crude oil transportation by rail.

- Bryan Naranjo, Norfolk Southern Railroad - Norfolk Sothern's Crude Oil by Rail Planning, Training and Response
- Mike Austin, CSX - CSX's Crude Oil by Rail Planning, Training and Response

1015

Break (20 mins.)

1035

Review of Workshop 1: Key Activities - Plenary

- Presentations by Subcommittees on oil behavior/transport; resources of concern; effects; and response options
- Conceptual models for the 5 Scenarios

1130

Work in between Workshops: Information Gathering (SEA) – Plenary

- Refined trajectory models for scenarios 1 and 3
- Extent of contamination maps
- Oil budgets (weathering effects in percentages of initial oil fate)
- Currents
- Nautical charts – Bathymetry/water depths
- ESI maps (based on topo sheets) for DE, PA and NJ – inventory of resources of concern
- Estuary sensitive areas maps – priority ecological resources by season ESI resources
- Extent of contamination maps
- M/V Athos oil spill after action report
- Maps of water intakes
- List of state endangered species from ACP (supplement those on the ESI maps)
- Estimates of bird and fish distributions (state reps and USFWS reps)
- MSDS for Bakken and Dilbit oils, 3 types of foam

1230

LUNCH (1 Hour) – provided

1330

Review Scenario 1: Conceptual Model for Human Health (Walker and Workgroup Coaches) - Plenary

- Applicable to all scenarios?
- Refine as necessary

1400

Review Risk Ranking: Threshold Levels of Concern (Walker, Clay Stern, USFWS and Kelly Scribner, CTEH) - Plenary

- Using thresholds to estimate the sensitivity to oil of the resources at risk
  - Exposure
  - Sensitivity
  - Effect
- Risk ranking matrix = thresholds for levels of concern to use in characterizing risk

1430

Characterize Risk of No Response Action (oil only, plus monitoring) – Workgroups

1530

BREAK (15 Mins)

1545

Begin characterizing risks of initial response actions (1st timeframe) - Workgroups

Characterize the relative risk for the response actions in the initial 2-6 hours of response

1645

Wrap-up for the Day

- Workgroup reports on progress - Plenary
- Introduction to tomorrow (Walker)
- Questions/discussion (all)

1700

ADJOURN

Workshop 2 - Day 2

June 24, 2015

0800

Overview for the day – Plenary

- Review the results of the first day
- Review process for today
    - Complete risk characterization (assign levels of concern) for response actions in both timeframes
    - Capture caveats – uncertainties, limitations
    - Summarize recommendations for response planning going forward
    - Questions, comments, adjustments?

0830

Complete 1st timeframe - Plenary

0915

Begin work on characterizing response action risks for 2nd timeframe – Workgroups

Characterize the relative risk for the response actions over the first 4-7 days of response

1015

BREAK (30 mins.)

1230

LUNCH (1 Hour) - provided

1330

Continue/complete characterization of risks for 2nd timeframe - Workgroups

1445

BREAK (then return to workgroup)

1520

Report out – risk ranking scores – Plenary

- **Limitations**
- **Uncertainty**
- **Response recommendations**

1600

Participant Feedback on ERA Process– Plenary

1615

Next steps– Plenary

1630

ADJOURN

Appendix D: Resources at Risk Table

Habitat	Sub habitats	Resource Category	Example Organisms (includes state-listed species)
On-land and on-water socio-economic areas	Work area (e.g., hot and warm zones), plus general public areas	Workers	First responders and pollution responders (on water/on land) involved in safety monitoring, oil recovery operations (on water/on land), oil contamination monitoring/SCAT
		Residential community	All - adults and adolescents; also children, elderly, and sick (single and multi-family residences)
		Sensitive receptors	Children, elderly, sick (daycares, hospitals, and nursing homes)
		Commercial community	Adults (retail, other commercial facilities)
		Industrial community	Adults (nearby refineries, plants, etc.)
		Transportation community	Potentially all (rail, marine, roads: drivers, passengers)
Artificial Shorelines	Bulkheads, riprap, manmade structures, pavement	Mammals, aquatic, and non-aquatic dependent	River otter, raccoon, muskrat, and bats
		Birds, aquatic, and non-aquatic dependent	Waterfowl, wading birds, shorebirds, song birds, raptors, and gulls
		Reptiles and amphibians	Diamondback terrapin, frogs, and salamanders
		Macro-invertebrates	Oysters, mussels, barnacles, crabs, and periwinkle
		Other invertebrates	Insects, spiders, and zooplankton
		T/E species - animals	Peregrine falcon and northern long-eared bat
		T/E species (or rare) - plants	None identified
Natural Terrestrial Shorelines	Vegetated (trees, shrub/scrub wetlands, grass), sand, and gravel	Mammals, aquatic, and non-aquatic dependent	River otter, raccoon, muskrat, and bats
		Birds, aquatic, and non-aquatic dependent	Waterfowl, wading birds, shorebirds, song birds, and raptors
		Reptiles and amphibians, aquatic and non-aquatic dependent	Diamondback terrapin, frogs, and salamanders
		Macro-invertebrates	Oysters, mussels, barnacles, dragonfly nymph, planktonic fish eggs, and crabs
		Aquatic vertebrates	Mummichog, Atlantic silverside, and bay anchovy
		T/E species - animals	Osprey, northern long-eared bat; also bald eagle still of concern although now recovered
		T/E species (or rare) - plants	Swamp pink, long-lobed arrowhead, wild rice, and swamp beggar-ticks

Habitat	Sub habitats	Resource Category	Example Organisms (includes state-listed species)
Intertidal Shoreline (Exposed & Sheltered) / Surface Water (0 to 1) meter	Marsh, swamp, tidal flats, sand beaches, cobble/boulder beach (at the water / land or water / air interface)	Mammals, aquatic and non-aquatic dependent	River otter, raccoon, muskrat, bats, and marsh rice rat
		Birds, aquatic and non-aquatic dependent	Waterfowl, wading birds, shorebirds, song birds, raptors, gulls
		Reptiles and amphibians	Diamondback terrapin, snapping turtle, and sea turtles
		Macro-invertebrates	Oysters, mussels, barnacles, dragonfly nymph, planktonic fish eggs, and horseshoe crabs
		T/E species - animals	Red knot, least bittern (shorebirds), southern leopard frog, and threespine stickleback
		T/E species - plants	Long-lobed arrowhead, wild rice, swamp beggar-ticks, seabeach amaranth, Wright's spike rush, Walter's barnyard grass, and Smith's bullrush
		Plants – submerged and floating aquatic vegetation	Water hyacinth, spatterdock, arrow arum, wild celery, and phytoplankton
		Fishing – commercial or recreational	Oysters, mussels, blue crab, flounder, bluefish, weakfish striped bass, and American shad
		Water intake - surface	Surface water – industrial or drinking water
Mid-water (0 to 2 meters)	Water column	Mammals, aquatic dependent	River otter
		Birds	Ducks, geese, cormorant, and gulls
		Reptiles	Snapping turtles and sea turtles
		Aquatic vertebrates	Mummichog, Atlantic silverside, bay anchovy
		Macro-invertebrates (incl. larval life stage)	Dragon fly nymph; larval clams, oysters, and crabs
		Plants – submerged and floating aquatic vegetation	Water hyacinth, spatterdock, arrow arum, wild celery, and phytoplankton
		T/E species - animals	Osprey, hickory shad, banded sunfish, threespine stickleback, and eastern redbelly turtle
		T/E species - plants	None identified
		Fishing – commercial and recreational	Oysters, mussels, blue crab, flounder, bluefish, weakfish, stripped bass, and American shad
		Water intakes - midwater	Surface water – industrial or drinking water

Habitat	Sub habitats	Resource Category	Example Organisms (includes state-listed species)
Benthic (bottom, >2 meters)	Attached or associated with the bottom of the water column / seabed	Aquatic vertebrates	Seals, river otter, mummichog, perch, sturgeon, sea turtles, dolphin, and porpoise
		Macro-invertebrates (incl. larval life stage)	Oysters, mussels, clams, worms, planktonic fish eggs, and crabs
		Aquatic invertebrates	Phytoplankton, zooplankton, and algae
		Plants – submerged aquatic vegetation	None identified
		T/E species - animals	Short-nosed sturgeon and Atlantic sturgeon
		T/E species - plants	None identified
		Fishing – commercial and recreational - bottom	Shrimp, scallop, and blue crab
		Water intakes - midwater	Industrial or drinking water

Appendix E: Response Actions Table

Summary of Response Actions	
Response Action	**No Response Action – Natural Attenuation and Monitoring**
Use	Natural attenuation relies on natural processes to decrease and "attenuate" concentrations of contaminants (oil) in soil, groundwater, and water. Monitoring typically involves collecting soil, groundwater, and water samples to analyze them for the presence of contaminants (oil) and other site characteristics. Allow natural attenuation for spills where oil is not recoverable and/or more environmental damage will occur from the response actions; or effective spill response resources are not available.
Examples/logistical considerations	Monitoring via sampling and other methods, networks of observers, sampling protocols, especially new methods for Group V oils (sunken dilbit crude oil after evaporation of light fractions).
Limitations	Environmental damage occurs to some extent. Public dissatisfaction with the oil spill response managers if dilbit oil sinks after light fractions evaporate and cannot be located or tracked; fisheries impacts.
Effectiveness	Attenuation may be prudent for Bakken crude oil. Dilbit being much more persistent will probably not be a candidate for attenuation on land. Monitoring would likely be required for both oil types; monitoring effectiveness over time on land will be more practical than in water.
Response Action	**Fire – Let Burn and Controlled Burn (both in-situ)**
Use	Allow rail cars to burn themselves out, or control the burn to reduce impacts of spilled oil to the environment.
Examples/logistical considerations	Water cooling streams, fireboats, air monitoring, and structural exposure protection.
Limitations	Access to water supply, frac tanks, high flow pumps, and nozzles.
Effectiveness	Ability to get close enough for effective cooling, potential for "heat-induced tear" in the shell of a rail car.
Response Action	**Fire – Extinguishing agent and methods**
Use	Strategies, methods, and people and equipment resources to extinguish a crude oil rail car fire.
Examples/logistical considerations	Foam availability to extinguish a rail car fire, and potential involvement of adjacent rail cars. Access to dry chemical agents, fire boom, and fire boats.
Limitations	Access to sufficient quantity of foam, dry chemical agents, fire boom, and fire boats. Need access to high volume fire pumps and nozzles. Requires highly skilled personnel.

Summary of Response Actions	
Effectiveness	Very effective if resources arrive quickly; before adjacent rail cars are heated and tears in shells of rail cars occur.
Response Action	**No Fire – Vapor Suppression**
Use	Use of a blanket of vapor suppression agents to reduce the vapors being released from pooled crude oil to reduce the risk of fire, and to provide a safe environment for the population and responders.
Examples/logistical considerations	Sufficient quantity of foam, and Subpart J products, such as herding agents, encapsulators, absorbents (Imbiber Beads), intrinsically safe vacuum pumps/trucks, PPE, and air monitoring.
Limitations	Foam application on a U.S. water body may not be allowed. Large area coverage may be needed. Applicator needs to be close enough, and have sufficient quantity to sustain coverage.
Effectiveness	Effective for pooled crude oil in containment (boom, drainage ditch, and small creek. Large area coverage is more difficult.
Response Action	**No Fire – Oil Spread Control – On land, on-water, underwater**
Use	Use of strategies, methods, and resources to control the spread of spilled crude oil on water.
Examples/logistical considerations	Containment/ deflection boom, sorbents, pneumatic curtains, turbidity curtain, dams/dikes, interceptor trenching, underflow dams, and pre-staged boom.
Limitations	Sufficient quantity boom, speed of deployment is critical to reduce spread, controlling spread of submerged oil is challenging, tide/current/ice can hamper control actions.
Effectiveness	Very effective if deployed correctly based on current speed. Turbidly, silt, and pneumatic curtain effectiveness may be impacted by current, and difficult to hold in place. Tidal range of Delaware River exposes mud flats at low tide.
Response Action	**No Fire – On-water Recovery, Underwater Recovery**
Use	Recovery of crude oil from water for disposal and possible reuse to prevent or minimize sensitive shoreline resources and habitat.
Examples/logistical considerations	Booms, self-propelled skimmers, stationary skimmers, and advancing skimmers (brush, drum, weir, and dynamic Inclined Plane). Collection booming, nets, trawls, pumps, dredge, divers, vacuum system, airlift, and bottom trawls.
Limitations	Type of skimmer must be selected for the type of oil. Submerged oil difficult to locate – impacting recovery methods. Low visibility will impair diver's ability to see oil. Recovery amount is encounter rate dependent.

Summary of Response Actions	
Effectiveness	Brush skimmers are very effective and efficient for heavy oils (dilbit). DIP and drum skimmer very effective for light oils (Bakken). Heavy sediment load and current in Delaware River can impact recovery of submerged oil. Diver effectiveness impaired by low visibility, and differentiating oil from mud.
Response Action	**No Fire – Resource Protection**
Use	Sensitive area protection strategies (ACP), protection booming strategies, deflection booming to protect sensitive areas, water intakes, and fisheries.
Examples/logistical considerations	12' boom for protection/deflection due to shallow water in Delaware River Creeks, and ease of use. 18" boom for deeper water areas. Turbidity and silt curtain used for submerged oil. Pneumatic curtains, dams/dikes, interceptor trenching, underflow dams, and pre-staged boom.
Limitations	Many sensitive areas identified in the ACP are creeks with shallow water. Exposed mud flats at low tide may impact placement of protection boom. Current and tide necessitates boom to be tended at every tide cycle. Many mid-river sites in the Delaware River have been tested for a spill scenario occurring in the River, but none have been tested for a spill source in the creeks. NJ shoreline along the Delaware Bay is very porous and difficult to protect.
Effectiveness	Protection strategies for floating oils are very effective in areas tested. Protection strategies for non-floating oils are much less effective.
Response Action	**No Fire – Shoreline Clean up**
Use	Removal of oil from the shoreline for disposal to prevent further contamination of sensitive areas and habitat.
Logistics	Mechanical recovery systems – skimmers, vacuum trucks, storage tanks, sorbent, hand tools, laborers, PPE, and Subpart J agents.
Limitations	Debris removal, recovery method based on shoreline type and oil type, access may be difficult, impacted habitat.
Effectiveness	Depends on many factors; oil type – heavy vs. light, amount of debris, and tide range impacts work schedule.
Response Action	**No Fire – Oil Detection/Mapping (physical contact methods)**
Use	Strategies, methods, and resources used to detect oil by physically sampling oil for movement, location, and physical properties.
Logistics	Water samples, trawls, underwater sentinels, monitoring stations, oil detection sensors, crab pots, Vessel Submerged Oil Recovery System (VSORS), snare samplers, and ROV.
Limitations	Develop sampling protocol to adequately cover the impacted areas, tide, and current spread oil quickly covering large areas. Determining sampling location may be difficult for

Summary of Response Actions	
	submerged oil, movement of oil depends on many factors – dynamic situation depends on conditions, e.g. winds, temp, and ice.
Effectiveness	Effectiveness limited by absence of a full suite of technological methods to detect oil and map its extent of contamination in all subsurface environments (water column or benthos). Some methods exist, but this is an active R&D area.
Response Action	**No Fire – Oil Detection/Mapping (remotely-observed methods)**
Use	Remotely monitor the movement of oil in the environment.
Logistics	Overflights and other visual observations, aircraft laser sensor, and other remote sensing systems (IR, FLIR), photo bathymetric, underwater visual by divers or ROV, sonar, laser fluorosensor, side-scan sonar, and multi-beam sonar.
Limitations	Availability of equipment and operator, data interpretation, and sampling protocol must be developed.
Effectiveness	Effectiveness limited by absence of a full suite technological methods to detect oil and map its extent of contamination in all subsurface environments (water column or benthos). Some methods exist, but this is an active R&D area.

Appendix F: Firefighting Foam MSDS

MATERIAL SAFETY DATA SHEET

ANSUL
by Tyco Fire Suppression & Building Products

PKW

Product Code: 2011-2-006 ANa Issue Date: 07-21-2010

1. Product and Company Identification

Material name	**PKW**
Version #	01
Revision date	07-21-2010
CAS #	Mixture
Product Code	2011-2-006 ANa
Product use	Fire extinguishing agent
Manufacturer / Importer / Supplier	
Name	Tyco Fire Suppression and Building Products
Address	One Stanton Street Marinette, WI 54143-2542
Phone	715-735-7411
Internet	http://www.ansul.com
Emergency Phone Number	CHEMTREC 800-424-9300 or 703-527-3887

2. Hazards Identification

Emergency overview	WARNING Irritating to eyes and skin. Prolonged exposure may cause chronic effects.
Potential health effects	
Routes of exposure	Eye contact. Skin contact. Inhalation. Ingestion.
Eyes	Contact with eyes may cause irritation.
Skin	Avoid contact with the skin. May cause skin irritation.
Inhalation	Inhalation of dusts may cause respiratory irritation.
Ingestion	Not a likely route of entry.
Target organs	Eyes. Respiratory system. Skin.
Signs and symptoms	Irritation of eyes and mucous membranes.

3. Composition / Information on Ingredients

Non-hazardous components	CAS #	Percent
Silicone fluid	63148-57-2	0.5 - 1.5
Purple Pigment	68647-14-3	1 - 5
MICA	12001-26-2	1 - 5
FULLERS EARTH	8031-18-3	1 - 5
POTASSIUM BICARBONATE	298-14-6	60 - 100

4. First Aid Measures

First aid procedures

Eye contact	Immediately flush eyes with plenty of water for at least 15 minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Get medical attention if irritation persists after washing.
Skin contact	Wash off with warm water and soap. Get medical attention if irritation develops and persists.
Inhalation	Move to fresh air.
Ingestion	Rinse mouth. Do not induce vomiting without advice from poison control center. If vomiting occurs, keep head low so that stomach content doesn't get into the lungs.

General advice	If you feel unwell, seek medical advice (show the label where possible). Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves. Show this safety data sheet to the doctor in attendance.

5. Fire Fighting Measures

Extinguishing media	
Suitable extinguishing media	This product is not flammable. Use extinguishing agent suitable for type of surrounding fire.
Protection of firefighters	
Specific hazards arising from the chemical	None known.
Protective equipment for firefighters	None known.
Special protective equipment for fire-fighters	None known.
Explosion data	
Sensitivity to mechanical impact	Not available.
Sensitivity to static discharge	Not available.
Hazardous combustion products	Carbon monoxide and carbon dioxide.

6. Accidental Release Measures

Personal precautions	Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Avoid inhalation of dust from the spilled material. Wear a dust mask if dust is generated above exposure limits.
Environmental precautions	Do not contaminate water.
Methods for containment	If sweeping of a contaminated area is necessary use a dust suppressant agent which does not react with the product. Prevent entry into waterways, sewer, basements or confined areas.
Methods for cleaning up	Should not be released into the environment. Sweep up or vacuum up spillage and collect in suitable container for disposal. Collect dust using a vacuum cleaner equipped with HEPA filter. Avoid the generation of dusts during clean-up. Clean up in accordance with all applicable regulations. Following product recovery, flush area with water.
Other information	Clean up in accordance with all applicable regulations.

7. Handling and Storage

Handling	Minimize dust generation and accumulation. Provide appropriate exhaust ventilation at places where dust is formed. Do not breathe dust. Avoid contact with eyes. Wash thoroughly after handling. Wear personal protective equipment.
Storage	Store in a well-ventilated place. Guard against dust accumulation of this material. Use care in handling/storage.

8. Exposure Controls / Personal Protection

Occupational exposure limits

Canada - British Columbia

Components	Type	Value	Form
MICA (12001-26-2)	TWA	3.0000 mg/m3	Respirable.

Canada - Ontario

Components	Type	Value	Form
MICA (12001-26-2)	TWA	3.0000 mg/m3	Respirable.

Canada - Quebec

Components	Type	Value	Form
MICA (12001-26-2)	TWA	3.0000 mg/m3	Respirable dust.

Personal protective equipment	
Eye / face protection	Wear safety glasses with side shields (or goggles).
Skin protection	Wear chemical protective equipment that is specifically recommended by the manufacturer. It may provide little or no thermal protection.
Respiratory protection	In the case of respirable dust and/or fumes, use self-contained breathing apparatus.

9. Physical & Chemical Properties

Appearance	
Form	Powder.
Color	Violet.
Odor	Odorless.
Physical state	Solid.
pH	Not available.
Melting point	Not available.
Freezing point	Not available.
Boiling point	Not available.
Flash point	Not available.
Evaporation rate	Not available.
Flammability limits in air, upper, % by volume	Not available.
Flammability limits in air, lower, % by volume	Not available.
Vapor pressure	Not available.
Vapor density	Not available.
Specific gravity	Not available.
Relative density	Not available.
Solubility (water)	Not available.
Partition coefficient (n-octanol/water)	Not available
Auto-ignition temperature	Not available.
Decomposition temperature	Not available.

10. Chemical Stability & Reactivity Information

Chemical stability	Material is stable under normal conditions.
Incompatible materials	Strong acids.
Hazardous decomposition products	Carbon oxides.

11. Toxicological Information

Toxicological information	The toxicity of this product has not been tested.
Chronic effects	Prolonged inhalation may be harmful. Not expected to be hazardous by WHMIS criteria.

12. Ecological Information

Ecotoxicity	This product has no known eco-toxicological effects.
Persistence and degradability	Not available.
Partition coefficient (n-octanol/water)	Not available

13. Disposal Considerations

Disposal instructions	Dispose of contents/container in accordance with local/regional/national/international regulations. Dispose of waste material according to Local, State, Federal, and Provincial Environmental Regulations.
Waste from residues / unused products	Dispose of in accordance with local regulations.

14. Transport Information

TDG

Not regulated as dangerous goods.

15. Regulatory Information

Canadian regulations This product has been classified in accordance with the hazard criteria of the CPR and the MSDS contains all the information required by the CPR.

WHMIS status Non-controlled

Inventory status

Country(s) or region	Inventory name	On inventory (yes/no)*
Australia	Australian Inventory of Chemical Substances (AICS)	No
Canada	Domestic Substances List (DSL)	No
Canada	Non-Domestic Substances List (NDSL)	Yes
China	Inventory of Existing Chemical Substances in China (IECSC)	No
Europe	European Inventory of Existing Commercial Chemical Substances (EINECS)	Yes
Europe	European List of Notified Chemical Substances (ELINCS)	No
Japan	Inventory of Existing and New Chemical Substances (ENCS)	No
Korea	Existing Chemicals List (ECL)	No
New Zealand	New Zealand Inventory	No
Philippines	Philippine Inventory of Chemicals and Chemical Substances (PICCS)	No
United States & Puerto Rico	Toxic Substances Control Act (TSCA) Inventory	Yes

*A "Yes" indicates that all components of this product comply with the inventory requirements administered by the governing country(s)

16. Other Information

Further information HMIS® is a registered trade and service mark of the NPCA.

HMIS® ratings
Health: 1
Flammability: 0

The information given is designed only as a guidance for safe handling, use, processing, storage, transportation, disposal and release and is not to be considered a warranty or quality specification. The information relates only to the specific material designated and may not be valid for such material used in combination with any other materials or in any process, unless specified in the text.

Issue date 07-21-2010

Thunderstorm FC-601A

MATERIAL SAFETY DATA SHEET

Date Prepared: 3/26/2010
Supersedes Date: New

1. CHEMICAL PRODUCT AND COMPANY IDENTIFICATION

Product Name: **Thunderstorm FC-601A**

Chemical Family: Surfactant mixture, fire fighting foam concentrate, aqueous film forming foam.

Company Identification: Chemguard, Inc.
204 South 6th Avenue
Mansfield, Texas 76063 USA
(817) 473-9964 (For Product Information)
(817) 473-9964 (For Emergency Information)
www.chemguard.com

2. COMPOSITION / INFORMATION ON INGREDIENTS

CONTAINING: HAZARDOUS AND/OR REGULATED COMPONENTS

Chemical Name	Percentage	CAS Number	OSHA Hazard
Water	Balance	7732-18-5	NO
Diethylene glycol monobutyl ether	4 – 13 %	112-34-5	YES
Polysaccharide gum	1 – 2 %	Proprietary	YES
Proprietary hydrocarbon surfactants	NA	Proprietary	YES
Proprietary fluorosurfactants	NA	Proprietary	YES

COMPOSITION NOTES:

3. HAZARDS IDENTIFICATION

EMERGENCY OVERVIEW
WARNING! MAY CAUSE EYE AND/OR SKIN IRRITATION

Routes of Exposure:

Eye Contact: Exposure during the handling or mixing may cause immediate or delayed irritation or inflammation.

Skin Contact: Exposure during the handling or mixing may cause immediate or delayed irritation or inflammation.

Ingestion: Ingestion of large quantities may cause abdominal cramps, nausea, vomiting, diarrhea.

Inhalation: Exposure to this product in excess of the applicable TVL or PEL may cause or aggravate other lung conditions. Exposure to this product may cause irritation to the nose, throat, and upper respiratory system.

Chronic: None known

Medical Conditions which May be Aggravated by Inhalation or Dermal Exposure: Persons with unusual (hyper) sensitivity to chemicals may experience adverse reactions to this product.

Carcinogenic Potential: This product and its ingredients are not listed as a carcinogen by NTP, OSHA, ACGIH or IARC.

4. FIRST AID MEASURES

Eyes: Immediately flush eyes thoroughly with water. Continue flushing eye for at least 15 minutes, including under lids. Seek immediate medical attention.

Skin: In case of contact, immediately wash with plenty of soap and water for at least 5 minutes. Seek medical attention if irritation or redness occurs. Remove contaminated clothing and shoes. Clean contaminated clothing and shoes before re-use.

Ingestion: If victim is conscious and alert, give 2 – 3 glasses of water to drink. Do not induce vomiting without medical advice. Do not induce vomiting or give anything by mouth to an unconscious person. Seek immediate medical attention. Do not leave victim unattended. Vomiting may occur spontaneously. To prevent aspiration of swallowed product, lay victim on side with head lower than waist. If vomiting occurs and the victim is conscious, give water to further dilute the chemical.

Inhalation: If respiratory irritation or distress occurs remove victim to fresh air. Seek medical attention if respiratory irritation or distress continues. If breathing is difficult, give oxygen. If breathing as ceased apply artificial respiration using oxygen and a suitable mechanical device such as a bag and a mask.

Notes to Physician: All treatments should be based on observed signs and symptoms of distress in the patient. Consideration should be given to the possibility that overexposure to materials other than this product may have occurred.

5. FIRE FIGHTING MEASURES

Flash Point – No flash to boiling

Lower Explosive Limit – Not Applicable
Upper Explosive Limit – Not Applicable
Hazardous Combustion Products – None known
Unusual Fire & Explosion Hazards – Decomposition products may be toxic.

Extinguishing Media – Water, Foam, Carbon Dioxide, Dry Chemical, Halon
Special fire fighting Procedures – None
Auto Ignition Temperature – Not Applicable

6. ACCIDENTAL RELEASE MEASURES

Wear appropriate protective gear for the situation. See Personal Protection information in section 8.

Containment of Spill: Dike or retain dilution water or water from firefighting for later disposal. Follow procedure described below under cleanup and disposal of spills.

Cleanup and Disposal of Spill: Vacuum or pump into an appropriate storage container. For smaller spills use absorbent materials and dispose of properly. Washing area with water will create large amounts of foam.

Environmental and Regulatory Reporting: Runoff from fire control or dilution water may cause pollution. Spills may be reportable to the National Response Center (800-424-8802) and to state and/or local agencies.

7. HANDLING AND STORAGE

Minimum/Maximum Storage Temperature: Store at temperatures of 35°F - 120°F.

Handling: Use with adequate ventilation.

Storage: Store in an area that is dry, well ventilated and in closed containers.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

Engineering Controls: Where engineering controls are indicated by use conditions or a potential for excessive exposure exists, the following traditional exposure techniques may be used to effectively minimize employee exposures.

Eye Protection: When engaged in activities where product could contact the eye, wear safety glasses with side shields, goggles, or face shield.

Skin Protection: Skin contact should be minimized through use of latex gloves and suitable long sleeved clothing. Consideration must be given both to durability as well as permeation resistance.

Respiratory Protection: Avoid actions that cause dust exposure to occur. Use local or general ventilation to control exposures below applicable exposure limits. NIOSH or MSHA approved particulate filter respirators should be used in the context of respiratory protection program meeting the requirements of the OSHA respiratory protection standard [29 CFR 1910.134] to control exposures when ventilation or other controls are inadequate or discomfort or irritation is experienced. Respirator and/or filter cartridge selection should be based on American National Standards Institute (ANSI) Standards Z88.2 Practices for Respiratory Protection.

Ventilation: Use local exhaust or general dilution ventilation to control exposure within applicable limits.

Work Practice Controls:

Personal hygiene is an important work practice exposure control measure and the following general measures should be taken when working with or handling this material:

(1) Do not store, use, and/or consume foods, beverages, tobacco products, or cosmetics in areas where this material is stored.
(2) Wash hands and face carefully before eating, drinking, using tobacco, applying cosmetics, or using the toilet.
(3) Wash exposed skin promptly to remove accidental splashes or contact with this material.

9. PHYSICAL AND CHEMICAL PROPERTIES

Appearance – Thick liquid
Odor – Very slight solvent odor
Physical State – Liquid
Specific Gravity (H2O=1) – 1.021 – 1.051
pH 7.0 – 8.5

Vapor Pressure – Not Evaluated
Density – Not Evaluated
Boiling Point – 212°F
Melting Point – 32°F
Solubility in Water – 100% Soluble

10. STABILITY AND REACTIVITY

Stability: Stable.

Conditions to avoid: Unintentional contact with water.

Hazardous Polymerization: Hazardous polymerization will not occur.

Incompatibility with other materials: Strong oxidizers

Hazardous Decomposition: Oxides of nitrogen, sulfur, carbon.

11. TOXICOLOGICAL INFORMATION

Acute Eye and Skin Toxicity Data:
Toxicological Information and Interpretation:

	Concentration	Solution (As Used)
Eye Irritation:	Not evaluated	Not evaluated
Skin Irritation:	Not evaluated	Not evaluated

Acute Dermal LD50
Acute Oral Effects:
Acute Oral LD50
Inhalation Toxicity: Not evaluated
Sensitization: Not evaluated
Teratology: Not evaluated
Mutagenicity: Not evaluated
Reproduction: Not evaluated

Chronic Toxicity:
This product does not contain any substances that are considered by OSHA, NTP, IARC or ACGIH to be "probable" or "suspected" human carcinogens.

12. ECOLOGICAL INFORMATION

Chemical Oxygen Demand: 304,000 mg/kg
Biological Oxygen Demand (5 Day) 141,000 mg/kg
Biodegradability (B.O.D./C.O.D.) 46%

13. DISPOSAL CONSIDERATIONS

Waste Disposal: Chemical additions, processing or otherwise altering this material may make the waste management information presented in this MSDS incomplete, inaccurate or otherwise inappropriate. Dispose of waste material according to local, state and federal regulations. Discharge to waste treatment facilities only with permission. Anti-foam agents may be used to reduce foaming in the waste streams. Do not incinerate.

14. TRANSPORTATION INFORMATION

Hazardous Materials Description/Proper Shipping Name: NOT REGULATED

Hazard Class: Not Applicable

Identification Number: Not Applicable

Required Label Text: Not Applicable

Hazardous Substances/Reportable Quantities: Not Applicable

15. REGULATORY INFORMATION

FEDERAL REGULATORY STATUS:

Status under OSHA Hazard Communication Standard, 29 CFR 1910.1200: This product is considered a

"hazardous chemical" under this regulation, and does not need to be included in the employer's hazard communication program.

Reportable Quantities Under the Clean Water Act, CERCLA, and EPCRA, 40 CFR 117, 302 and 355:
The product contains no component regulated under section 304 (40 CFR 370).

Hazard Category and Applicability of EPCRA Hazardous Substance Inventory Reporting, 40 CFR 370:
Not listed

Applicability of EPCRA Toxic Chemical Release Inventory (TRI) Reporting. 40 CFR 372:
Not subject to TRI reporting

Status Under the Toxic Substances Control Act, 40 CFR 710:
All chemical(s) comprising this product are either exempt or listed on the TSCA Inventory.

SARA Title III Hazard Classes:

Fire Hazard:	NO
Reactive Hazard:	NO
Release of Pressure:	NO
Acute Health Hazard:	YES
Chronic Health Hazard:	NO

State Regulations:

California:
This product does not contain any components that are regulated under California Proposition 65.

Pennsylvania:
This product does not contain any components on the Pennsylvania Right to Know List.

16. OTHER INFORMATION

NFPA Ratings: Health: **1** Flammability: **0** Reactivity: **0**

Label Requirements:

WARNING! MAY CAUSE EYE AND/OR SKIN IRRITATION

Hazardous Material Information System (HMIS):	Health	1
	Flammability	0

	Personal Protection	A

NFPA/HMIS Definitions: 0-Least, 1-Slight, 2-Moderate, 3-High, 4-Extreme
Protective Equipment: Safety glasses, gloves

ADDITIONAL INFORMATION:

The information contained in this document is given in good faith and based on our current knowledge.

It is only an indication and is in no way binding, notably as regards infringement of, or prejudice to third parties through the use of our products. Chemguard guarantees that its products comply with its sales specifications. This information must on no account be used as a substitute for necessary prior tests which alone can ensure that a product is suitable for a given use. Users are responsible for ensuring compliance with local legislation and for obtaining the necessary certifications and authorizations.

END OF MSDS

National Foam

MATERIAL SAFETY DATA SHEET #NMS420

UNIVERSAL GOLD 1% / 3%

ALCOHOL RESISTANT AQUEOUS FILM FORMING FOAM (AR-AFFF)

Liquid Concentrate

Section 1. CHEMICAL PRODUCT/COMPANY IDENTIFICATION

Material Identification
Product: Universal Gold 3%, Fire Fighting Foam Concentrate
Synonyms: Alcohol Resistant Aqueous Film Forming Foam (AR-AFFF)
CAS No: Mixture - No single CAS # applicable

Company Identification
Manufacturer:
National Foam, Inc.
180 Sheree Boulevard, Suite 3900
Exton, PA 19341
Emergency Phone Number (Red Alert): (610) 363-1400 (U.S.A.)
Fax: (610) 524-9073
www.nationalfoam.com

Section 2. COMPOSITION / INFORMATION ON INGREDIENTS

Components	CAS Number	% Weight
Water	7732-18-5	80-93%
Proprietary mixture of synthetic detergents	No single CAS # applicable	4-10%
(2-Methoxymethylethoxy) Propanol	34590-94-8	2-5%
Fluoroalkyl Surfactant	Confidential	0.5-2.0%
Polysaccharide	11138-66-2	0.5-2.0%

Section 3. HAZARDS IDENTIFICATION

Potential Health Effects

Inhalation
Vapors are minimal at room temperature. If product is heated or sprayed as an aerosol, airborne material may cause respiratory irritation.

Skin Contact
Contact with liquid may cause moderate irritation or dermatitis due to removal of oils from the skin.

Eye Contact
Product is an eye irritant.

Ingestion
Not a hazard in normal industrial use. Small amounts swallowed during normal handling operations are not likely to cause injury; swallowing large amounts may cause injury or irritation.

Additional Health Effects
Existing eye or skin sensitivity may be aggravated by exposure.

Carcinogenicity Information
No data available.

Section 4. FIRST AID MEASURES

Inhalation
No specific treatment is necessary since this material is not likely to be hazardous by inhalation. If exposed to excessive levels of airborne aerosol mists, remove to fresh air. Seek medical attention if effects occur.

Skin Contact
In case of skin contact, wash off in flowing water or shower. Launder clothing before reuse.

Eye Contact
In case of eye contact, flush eyes promptly with water for 15 minutes. Retract eyelids often to ensure thorough rinsing. Consult a physician if irritation persists.

Ingestion
Swallowing less than an ounce is not expected to cause significant harm. For larger amounts, do not induce vomiting. Give milk or water. Never give anything by mouth to an unconscious person. Seek medical attention.

Section 5. FIRE FIGHTING MEASURES

Flammable Properties
Flash Point: >200°F

Fire and Explosion Hazards
Avoid contact with water reactive materials, burning metals and electrically energized equipment.

Extinguishing Media
Product is an extinguishing media. Use media appropriate for surrounding materials.

Special Fire Fighting Instructions
This product will produce foam when mixed with water.

Section 6. ACCIDENTAL RELEASE MEASURES

Safeguards (Personnel)
NOTE: Review FIRE FIGHTING MEASURES and HANDLING (Personnel) sections before proceeding with clean-up. Use appropriate Personal Protective Equipment during clean-up.

Accidental Release Measures

Concentrate
Stop flow if possible. Use appropriate protective equipment during clean up. For small volume releases, collect spilled concentrate with absorbent material; place in approved container. For large volume releases, contain and collect for use where possible. Flush area with water until it no longer foams. Exercise caution, surfaces may be slippery. Prevent discharge of concentrate to waterways. Disposal should be made in accordance with federal, state and local regulations.

Foam/Foam Solution
See above. Flush with water. Prevent discharge of foam/foam solution to waterways. Do not discharge into biological sewer treatment systems without prior approval. Disposal should be made in accordance with federal, state and local regulations.

Section 7. HANDLING AND STORAGE

Handling (Personnel)
Avoid contact with eyes, skin or clothing. Avoid ingestion or inhalation. Rinse skin and eyes thoroughly in case of contact. Review HAZARDS and FIRST AID sections.

Storage
Recommended storage environment is between 35°F (2°C) and 120°F (49°C). Store product in original shipping container or tanks designed for product storage.

Section 8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls
Special ventilation is not required.

Personal Protective Equipment

Respiratory
Recommended exposure limits (OSHA-PEL and ACGIH-TLV) have not been determined for this material. The need for respiratory protection should be evaluated by a qualified health specialist.

Protective Clothing
Rubber or PVC gloves recommended.

Eye Protection
Safety glasses, face shield or chemical splash goggles must be worn when possibility exists for eye contact. Contact lenses should not be worn. Eye wash facilities are recommended.

Other Hygienic Practices
Use good personal hygiene practices. Wash hands before eating, drinking, smoking, or using toilet facilities. Promptly remove soiled clothing and wash thoroughly before re-use.

Exposure Guidelines

Exposure Limits
(2-Methoxymethylethoxy) Propanol (34590-94-8)

PEL(OSHA)
100 ppm, 8 hr. TWA Skin
150 ppm, 15 min. STEL Skin

TLV (ACGIH)
100 ppm, 8 hr. TWA Skin
150 ppm, 15 min. STEL Skin

Section 9. PHYSICAL AND CHEMICAL PROPERTIES

Physical Data

Boiling Point:	Not applicable
Vapor Pressure:	Not applicable
Vapor Density:	Not applicable
Melting Point:	Not applicable

Evaporation Rate:	<1 (Butyl Acetate = 1.0)
Solubility in Water:	100%
pH:	8.0
Freezing Point:	26°F (-3°C)
Specific Gravity:	1.025 @ 25°C
Odor:	Mild, pleasant
Form:	Viscous liquid
Color:	Amber

Section 10. STABILITY AND REACTIVITY

Chemical Stability
Stable.

Incompatibility, Materials to Avoid
Avoid use of product on burning metals, electrically-energized equipment and contact with water reactive materials.

Polymerization
Will not occur.

Section 11. TOXICOLOGICAL INFORMATION

Mammalian Toxicity

Ingestion
This material was not toxic when administered to Wistar Albino rats at an acute oral dose of 5g/kg body weight.

Eye
Animal testing indicates this material is a primary eye irritant when tested undiluted on New Zealand Albino Rabbits.

Skin
Animal testing indicates this material is not a primary skin irritant when tested undiluted on New Zealand Albino Rabbits.

Inhalation
No data available at this time.

Carcinogenic, Developmental, Reproductive, Mutagenic Effects
No data available on this material.

Section 12. ECOLOGICAL INFORMATION

Ecotoxicological Information Aquatic Toxicity
96 hr. Flow Through LC_{50} for Fathead Minnows (pimephales promelas) is reported to be greater than 500 ppm.

Environmental Fate

BOD_5	Concentrate	91,500 mg/kg
COD	Concentrate	290,000 mg/kg

Section 13. DISPOSAL CONSIDERATIONS

Universal Gold, as sold, is not a RCRA-listed waste or hazardous waste as characterized by 40 CFR 261. However, State and local requirements for waste disposal may be more restrictive or otherwise different from Federal regulations. Therefore, applicable local and state regulatory agencies should be contacted regarding disposal of waste foam concentrate or foam/foam solution.

Concentrate
Do not discharge into biological sewer treatment systems without prior approval. Specific concerns are high BOD load and foaming tendency. Low dosage flow rate or antifoaming agents acceptable to the treatment plant may be helpful. Do not flush to waterways. Disposal should be made in accordance with federal, state and local regulations.

Foam/Foam Solution
Universal Gold foam solution can be treated by waste water treatment facilities. Discharge into biological sewer treatment facilities may be done with prior approval. Specific concerns are high BOD load. Dilution will reduce BOD and COD factors proportionately. Low dosage flow rate or antifoaming agents acceptable to the treatment plant may be helpful. Do not flush to waterways. Disposal should be made in accordance with federal, state and local regulations.

NOTE: As a service to our customers, National Foam has approvals in place with disposal facilities throughout the U.S. for waste water treatment and solidification and landfill of our foam liquid concentrates and foam solutions. If required, National Foam, Inc. can also provide information on the disposal of drums used for shipping our concentrates. Please contact National Foam's Risk Management Administrator at (610) 363-1400 for additional information.

Section 14. TRANSPORTATION INFORMATION

Shipping Information
Proper Shipping Name: Fire Extinguisher Charges or Compounds N.O.I., Class 70
National Motor Freight Code: 69160 Sub 0
Hazard Class: None
UN Number: None

Section 15. REGULATORY INFORMATION

U.S. Federal Regulations

Toxic Substances Control Act (TSCA)
All components of this product are listed in the TSCA inventory.

Superfund Amendments and Reauthorization Act of 1986 (SARA), Title III

Section 302/304
There are no components of this material with known CAS numbers which are on the Extremely Hazardous Substances (EHS) list.

Section 311 & 312
Based on available information, this material contains the following components which are classified as the following health and/or physical hazards according to Section 311 & 312:
(2-Methoxymethylethoxy) Propanol 34590-94-8 (Flammability)

Section 313
This material does not contain any chemical components subject to Section 313 reporting requirements.

COMPREHENSIVE ENVIRONMENTAL RESPONSE, COMPENSATION, AND LIABILITY ACT (CERCLA)
This material does not contain any components subject to the reporting requirements of CERCLA.

OTHER REGULATORY INFORMATION
Canadian Environmental Protection Act (CEPA). All ingredients are listed on the DSL (Domestic Substance List).

STATE REGULATIONS

PENNSYLVANIA RIGHT-TO-KNOW HAZARDOUS SUBSTANCES LIST

PA Hazardous Substances present at levels greater than 1%:
(2-Methoxymethylethoxy) Propanol 34590-94-8

Section 16. OTHER INFORMATION

NFPA Rating	WHMIS Rating
Health 0 Flammability 0 Reactivity 0	D2B

ADDITIONAL INFORMATION

Preparation Date/Revision Number.....10/24/13

For further information, see National Foam Product Data Sheet for Universal Gold 1% / 3%.

The information contained herein is furnished without warranty either expressed or implied. This data sheet is not a part of any contract of sale. The information contained herein is believed to be correct or is obtained from sources believed to be generally reliable. However, it is the responsibility of the user of these materials to investigate, understand and comply with federal, state and local guidelines and procedures for safe handling and use of these materials. National Foam, Inc. shall not be liable for any loss or damage arising directly or indirectly from the use of this product and National Foam, Inc. assumes no obligation or liabilities for reliance on the information contained herein or omissions herefrom.

October 24, 2013

Appendix G: Conceptual Models

Conceptual Model:

The conceptual model depicts the connections between the resources of concern (human health/socio-economic and ecological) and their potential to be exposed to hazards (exposure pathway) for 5 incident scenarios. The numbers in the cells represent the path by which a hazard can affect a resource. This is our record of our reasoning about the concern for that resource. NA represents the absence of a connection between a potential hazard and the resource of concern.

Hazards/exposure pathways:

1. Air pollution – vapors, direct affects from respiratory issues for air breathers.
2. Aqueous exposure – direct affects from aquatic respiration and dermal exposure to oil and oil components dissolved within the water column; may be short-lived exposure with the potential for high consequence for impacted species. Excludes submerged oil globules.
3. Physical trauma (mechanical impact from equipment, aircraft, people, boats, etc.) – direct affects from physical impact on individual species.
4. Oiling/smothering – direct affects from dermal contact with oil; skin (hypothermia), mucosal membranes (eyes, nares, etc.); indirect affects or secondary impacts could include ingestion (preening). May include contact with submerged oil globules.
5. Thermal (heat exposure from fire) – direct affects from oil burning; impacts from exposure to a fire/burn (not dermal exposure to the oil).
6. Waste – direct affects from being removed and managed from the system
7. Ingestion (food web, etc.) – resources indirectly exposed to oil or its constituents via ingestion of oil or contaminated/affected prey.
8. Advisory/Closure – prohibit action of use (e.g., commercial or recreational fishery, water intake); protection from possible exposure. N/A = no interaction or no effect

Oil Type:

B1 = Bakken – surface;
B2 – Bakken within water column due to natural dispersion; D1 = Dilbit before evaporation of light fractions;
D2 = Dilbit after evaporation of light fractions

BAKKEN Oil Characteristics: It will quickly spread into thin slicks, with significant amounts of the lighter fractions lost via evaporation (which can result in serious explosion/fire and inhalation risks). Bakken crude contains moderate concentrations of toxic (soluble) compounds, thus can poses risks to aquatic resources. In addition, it will oil and penetrate into intertidal habitats, causing the potential for fouling of riverine habitats and long-term contamination of sediments.

DILBIT Oil Characteristics: Diluted bitumen, or dilbit, is bitumen, a heavy oil, that has been blended with one or more light petroleum products, such as condensate (the oil co-produced from a gas well) or a naphtha-based oil. Once released, dilbit will initially behave as a medium crude oil. However, it will rapidly lose the volatile fraction of the diluent through evaporation, leaving behind the viscous bitumen. The diluents have high percentages of toxic, water- soluble components, resulting in greater risks to water-column organisms compared to heavier oils. Acutely toxic impacts from the diluent could be relatively severe, but limited to a localized area. Depending on the density of the bitumen, the residue may float or sink; depending on the viscosity, pour point, and ambient temperatures, they will spread into slicks or congeal into tarballs and tarmats; depending on what they were blended with, they can change properties over time. SCAT and Operations teams should be asked to observe and report any burial or sinking.

SCENARIO 1 Conceptual Model: Human Health/Socio-economic Resources of Concern

Habitat	Human Health and Safety					
Sub habitats	Work Area (e.g., hot and warm zones), plus Public Health (Transportation, Industrial, Residential/Recreational Communities)					
Oil Type	B1	B1	B1	B1	B1	B1
Resources of Concern (Socio- economic)	Workers	Residential Community	Sensitive Receptors	Commercial Community	Industrial Community	Transportation Community
Human health and safety receptors relevant to this ERA	First responders (on water/on land), safety monitoring, oil recovery operations (on water/on land), oil contamination monitoring/SCAT	All - Adults, Adolescents; also children, elderly, sick (Personal Residences)	Children, Elderly, Sick (Daycares, Hospitals, Nursing Homes)	Adults (Shops, General Commercial Facilities)	Adults (Nearby Refineries, Plants, etc.)	Mostly Adults (rail, marine, roads: drivers, passengers)
Response Actions - Actionable Oil						
No response action except monitoring (air: flammability, benzene, etc.; soil; water; and stranded onshore oil)	1,3,8	1, 8	1, 8	1, 8	1, 8	
Fire						
Let burn and controlled burn (both in-situ)	1,3, 5,8	1,5,7,8	1,5,7,8	1,5,7,8	1,5,7,8	
Extinguishing agents and methods	1,3, 5,8	1,5,7,8	5,7,8	1,5,7,8	1,5,7,8	
No Fire						
Vapor suppression	1,3,8	1,7,8	1,7,8	1,7,8	1,7,8	
Oil spread control	1,3,6,8	1,8	1,8	1,7,8	1,7,8	
On-water oil recovery	1,3,6,8	1,8	1,8	1,8	1,8	
Resource protection	1,3,6,8	1,8	1,8	1,8	NA	
Shoreline clean up	1,3,6,7,8	1,8	1,8	1,8	1, 2, 7	
Oil Detection/mapping - **remotely observed methods**	NA	NA	NA	NA	NA	

SCENARIO 1 Conceptual Model: Ecological Resources of Concern

Habitat	Artificial Shorelines						Natural Terrestrial Shorelines						Intertidal Shoreline (Exposed & Sheltered) / Surface Water (0 - 1 meter)								Mid-water (0 to 2 meters)								Benthic (bottom, >2 meters)							
Sub habitats	Bulkheads, Riprap, Manmade Structures, Pavement						Vegetated (Trees, shrub/scrub wetlands, etc.), Grass, Sand, Gravel						Marsh, Swamp, Tidal flats, Sand Beaches, Cobble/Boulder Beach (at the water / land or water / air interface)								Water Column								(Attached or associated with the Bottom of the Water Column / Seabed)							
Oil Type	B1	B1	B1	B1	B1	B1	B1	B1	B1	B1	B1	B1	B1/B2	B1/B2	B1/B2	B1/B2	B1/B2	B1/B2	B1/B2	B1/B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2	B2

Oil Weathering Graphs – Scenario 1 (from ADIOS2):

- **Oil Type**
  - BAKKEN, ANALYSIS OF OIL FROM LAC-MEGANTIC DERAILMENT
  - Location = none listed
  - Synonyms = none listed
  - Product Type = crude
  - API = 41.8
  - Pour Point = unknown
  - Flash Point = unknown
  - Density = 0.827 g/cc at 50 deg F
  - Viscosity = 3.6 cSt at 50 deg F
  - Adhesion = unknown
  - Aromatics = unknown
- **Emulsification**
  - Mousse begins to form when 100% of the oil has evaporated.
- **Wind and Wave Conditions**
  - Wind Speed = 6 mph from 0 degrees
  - Wave Height = computed from wind speed, unlimited fetch (default)
- **Water Properties**
  - Temperature = 50 deg F
  - Salinity = 0 ppt
  - Sediment Load = 50 g/m3 (avg. river/estuary)
  - Current = 0.5 mph towards 0 degrees
- **Release Information**
  - **Instantaneous Release**
    - Time of Release = January 15, 0500 hours
    - Amount Spilled = 50000 gal

Appendix I: Summary of Online CERA Survey Results

SEA developed on online evaluation in Survey Monkey for workshops participants, which was emailed to them on July 21, 2015. Because very few participants completed the workshop feedback form distributed at the end of the second workshop, the Project Committee conducted the online ERA survey.

Statistical Results

- 100% of participants surveyed gained useful information from the workshops, with an opportunity to provide open comments.
- 83% of participants felt the ERA Workshops were either very effective or effective in accomplishing the aim of assessing and reaching consensus about the potential risks of responding to Bakken and dilbit oils in the five Delaware Bay and River scenarios.
- 83% of participants felt the lead facilitator's ability to communicate and guide this ERA process was excellent or very good.
- All participants thought resource materials were helpful, although 25% thought they were moderately to slightly helpful.
- Regarding workgroup structure and engagement, about 33% thought it was excellent, 33% very good, and 33% good.
- Two-thirds thought the workshop was the right length; but a third of participants thought the workshops were too long.
- 57% of participants thought the workshop's objectives were extremely or very clear.

Comments

What components of the workshops did you find most valuable?

- I knew little about oil and related issues so I learned a lot.
- The discussions within the scenario small groups regarding impacts on sensitive resources from different response alternatives.
- The one day information sessions that began the workshop were valuable.
- Talks by subject experts.
- Diversity of opinions of the participants.
- Technical updates and presentations.
- The group interaction and discussions.
- Understanding others' points of view.
- Discussions and deliberations during the group breakouts.

What components of the workshops did you find least valuable?

- Visual aids. They were not large enough.
- Some of the posters and slides were difficult to see.
- Scenario workgroups (i.e., breakout sessions). The directions and assumptions for evaluating risk could have been clearer and better guided.
- The long days.
- Some of the presentations, while interesting, took time away from the breakout sessions.

Was the length of the workshops appropriate?

- It was really hard to give up 3 entire days- it seemed like the science community could have come together to discuss their issues a little more before the rest of us joined in.
- No, but only because I could not make the second two days. More notice would have been better.
- 4 days was too much time. I was unable to attend the workshop in its entirety.
- The days could have been shortened.

Is there anything else you'd like to share about the ERA Workshops?

- We need more of them.
- Overall, I like the idea of having all the players in one room to gain consensus. The execution of day two could have been better. Thank you for taking the time to put this together. It was valuable to me for assessing the risks of Oil by Rail in our region.
- Nice interaction by all. More involvement by the Railroads Operational and HAZMAT staffs and their contribution to the increase of oil movement by rail.

Feedback at the Workshop

The most common comments submitted on the feedback form following the workshops were:

- More time in workgroups, less time in plenary sessions.
- More structure to workgroups, e.g., common ground rules, better division of individuals per group.
- Participants wanted to know more about Bakken and dilbit, e.g., fate, transport, behavior, toxicity, and impact on animals in the water column.
- Participants learned a lot from the presentations by the rail companies on rail operations and response.
- Working with 5 scenarios may be too ambitious, not able to get in-depth into the scenarios or compare amongst groups.

Fowlers Beach

Bioremediation of Experimental Oil Spill on Delaware's Shoreline

Environ. Sci. Technol. **1996**, *30,* 1764−1775

Bioremediation of an Experimental Oil Spill on the Shoreline of Delaware Bay

In the summer of 1994, a field study was undertaken in Delaware in which light crude oil was intentionally released onto plots to evaluate bioremediation. The objectives were to obtain credible statistical evidence to determine if bioremediation with inorganic mineral nutrients and/or microbial inoculation enhanced the removal of crude oil contaminating a sandy beach and to compute intrinsic and enhanced biodegradation rates. Biodegradation was tracked by GC/MS analysis of selected components, and the measured concentrations were corrected for abiotic removal by hopane normalization. A randomized block design was used to assess treatment effects. Three treatments were evaluated: a no-nutrient addition control, addition of water-soluble nutrients, and addition of water-soluble nutrients supplemented with a natural microbial inoculum from the site. Although substantial hydrocarbon biodegradation occurred in the untreated plots, statistically significant differences between treated and untreated plots were observed in the biodegradation rates of total alkane and total aromatic hydrocarbons. First-order rate constants for the disappearance of individual hopane-normalized alkanes and PAHs were computed, and the patterns of loss were typical of biodegradation. Significant differences were not observed between plots treated with nutrients alone and plots treated with nutrients and the indigenous inoculum. The high rate of oil biodegradation that was observed in the untreated plots was attributed to the background nitrogen that was measured at the site. Even though oil loss was enhanced by nutrient addition, active bioremediation in the form of exogenous nutrient addition might not be appropriate in cases where background nutrient levels are already sufficiently high to support high intrinsic rates of hydrocarbon biodegradation.

Introduction

A number of studies of oil spill bioremediation on marine shorelines have been conducted (*1*−*13*). These studies have concluded that bioremediation enhances the removal of crude oil several times more than the intrinsic rate. Much skepticism remains in the field, however, because data from all of these investigations have been equivocal to some extent. One reason for the uncertainty is a fundamental flaw in the experimental design of many of these studies. That is, the studies usually used pseudoreplication to test for treatment effects, in which either the treatments were not replicated or replicates were not statistically independent (*14*). The pseudoreplicate designs usually resulted from intense subsampling of unreplicated plots (*1*, *2*, *8*−*11*, *13*). Without full replication and random interspersion of treatments, it is impossible to ascribe statistically significant differences in the response variable(s) to the treatments (*14*). The reason is simply that unknown, uncontrollable variables (unidirectional longshore currents, spatially distinct underground flows, prevailing winds, etc.) may exist in different parts of the same experimental area that may impart bias to one of the treatments. The only way to control this is to replicate the treatments and to randomly locate and interdisperse them on the experimental plane. Then, if systematic geomorphological or other physical biases exist in certain areas, the statistical analysis can easily account for them. Two studies that used proper replication and randomization to demonstrate significant treatment effects were conducted in terrestrial environments rather than on marine beaches (*15*, *16*). Since the physical factors affecting oil and nutrient removal, as well as the persistence of introduced microorganisms, are so different in terrestrial and beach ecosystems, it is not possible to extrapolate from these studies to conclude that bioremediation will also be effective on oil-contaminated coasts.

Another problem common to many field studies is the differences in the way the treated and control plots are manipulated (*1*, *2*, *8*−*11*, *13*). It is important to keep experimental manipulation of the treatments identical except for the one variable being tested, otherwise differences cannot be attributed unambiguously to the process being evaluated. For example, in one of the studies (*8*), the control plot was unamended and untouched whereas the treated plot was watered and tilled daily in addition to the nutrient and microbial amendments. This confounds conclusions regarding the cause of any observed differences.

Two recent reports have pointed to the need for more controlled studies of bioremediation for cleanup of oil-contaminated beaches (*17*, *18*) because the current database is inadequate to provide guidance to spill responders. In particular, the relative advantages of biostimulation (i.e.,

addition of nutrients alone) and/or bioaugmentation (addition of nutrients plus hydrocarbon-degrading bacteria) need further study (*17*). The goals of this project were to quantify the effectiveness of intrinsic biodegradation due to natural levels of background nutrients already present in the Fowler Beach area of Delaware Bay, to demonstrate the effectiveness of biostimulation and/or bioaugmentation, to determine the extent of any resulting rate enhancement, and to provide guidelines that can be used by spill responders and on-scene coordinators for the effective bioremediation of oil-contaminated sandy shores. Other goals were to quantify the biological effects of the oil and of the bioremediation treatments using various types of toxicity bioassays. Preliminary results of the toxicology work have been published elsewhere (*19*).

Since huge quantities of crude oil and refined petroleum products are transported through Delaware Bay each year, the State of Delaware is concerned about the ecological impact of a large oil spill in the area. Large quantities of migratory birds feed on the eggs deposited by horseshoe crabs (*Limulus polyphemus*) in the intertidal sands of the Delaware and New Jersey shores. Thus, an oil spill that occurred during spawning season could have catastrophic effects on these bird populations as well as future generations of horseshoe crabs.

Experimental Section

Approach. The null hypothesis was that biostimulation and/or bioaugmentation will not increase the rate or extent of removal of measured oil components over background. A randomized complete block design with repeated measures was used to assess treatment effects. Five areas of beach were selected based on the depth to a layer of peat below the surface of the sand that extended from a saltwater marsh several hundred meters west of the beach area. Each area ("block") was large enough to accommodate four experimental units or test plots. The blocks were situated in a row on the beach parallel to the shoreline. Three treatments were tested on oiled plots: a no-nutrient addition control, addition of water-soluble nutrients, and addition of water-soluble nutrients supplemented with a natural microbial inoculum from the site. A fourth treatment, an unoiled and untreated plot, served as a background control for the biological recovery studies. The four treatments were randomized in each of the five blocks.

Experience from previous studies (*20*−*22*) suggested that, to minimize edge effects in a small plot study such as this, oil should be applied near the spring high tide line. A schematic diagram of the block layout is summarized in Figure 1. The five blocks of four treatments were located on one long beach as shown. Each treatment plot measured 36 m^2 in area (4 m × 9 m). The distance between plots within a block was 10 m. The minimum distance between blocks was 10 m, although 104 m separated blocks 1 and 2 and 154 m separated blocks 4 and 5. The plots were laid out using standard surveying equipment. The top of each plot was positioned at the same elevation, measured relative to benchmarks (fence posts) placed on the high dune area, so that all plots would experience the same levels of submersion and exposure. Three steel fence posts were driven in the middle of each plot on a line bisecting the longitudinal axis of the plot. These were used to monitor the change in beach topography with time (by measuring the distance from the tops of the posts to the sand surface) as tide and wave action caused erosion and accretion of the sand within the plots. Such topographical alterations could artificially affect oil concentrations measured.

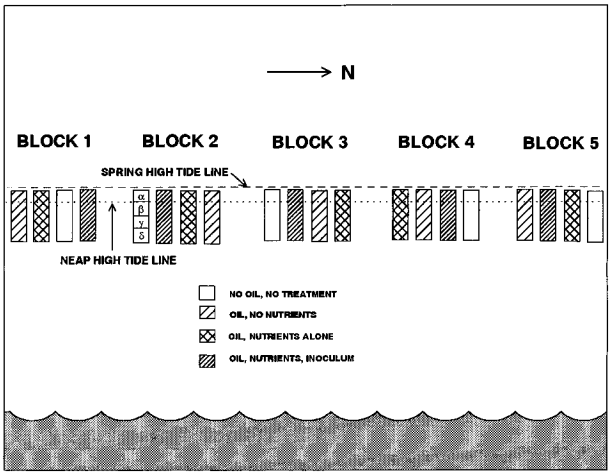

FIGURE 1. Layout of the randomized complete block design showing actual random order of plots on Fowler Beach.

Detailed Description of Blocks. Each block was equipped with its own gasoline-powered generator to supply power to four electric pumps, one for each of the four plots. The pumps supplied seawater with or without bioremediation amendments to their respective plots. Adjacent to each pump was a polyethylene reservoir holding 800 L of seawater containing the appropriate amendments for daily application to the plots. Slickbar booms were used to contain the oil and free-moving oiled sand within the plots. These booms were 30 m in length and contained 0.6 m long plastic floats riveted into a Kevlar skirted sheet extending about 0.6 m below the water surface. The booms were held in place between pairs of steel pipe driven approximately 1 m below the surface of the sand and spaced every 2.3 m around the perimeter of each plot. The booms floated on the water during flooding tides to contain floating oil and served as dams containing oiled sand when the tide ebbed. A sorbent boom was placed around the Slickbar boom as an added safety precaution in the event of an accidental release beyond the primary containment. The sorbent boom was removed several days after application of the oil, when floating oil was no longer observed. Length measurements were taken from the tops of the inner steel posts retaining the booms to the sand surface to supplement the beach topography data.

Application of Oil to Plots. The crude oil used was Bonny Light (Escravos), which is imported from Nigeria. It had a specific gravity of 0.848, API gravity of 35.3, Reed vapor pressure of 6.9, viscosity of 5.6 CST at 21 °C, a pour point of −3 °C, and a sulfur content of 0.11% by weight. It was weathered prior to application by placing about 3 m^3 in a 3.6 m diameter plastic tank, connecting a pump and hose, and continuously spraying and recirculating the oil within the tank for 2 days to evaporate the light fraction. Following this, the weathered oil was placed into 210-L drums (136 L/drum) to await application. Oil was applied manually by two four-membered teams on July 1, 1994. Two persons held onto each end of a 4 m length of pipe connecting a hose to a pump that led into the 210-L drum containing the oil. The oil was pumped through the hose out of four atomizer nozzles attached to the pipe manifold. The persons applying the oil walked slowly up and down the plot while a third person lifted the trailing hose over the steel pipe holding the containment booms in place. The

fourth person held a stopwatch and timed the walking pace of the appliers. The 136 L of oil was applied uniformly in 14 sweeps of the plot over a period of about 7 min. A total of 2040 L of crude oil was released onto the 15 plots.

Nutrient Application. The minimum nitrate concentration needed to support the maximum growth rate of alkane degraders under continuous flow conditions ranges between 0.5 and 2.5 mg of N/L (*23*). Since nitrate in the interstitial pore water is quickly diluted to background levels whenever the incoming tide completely submerges the plot (*24*), we applied nutrients every day. To achieve the target 1.5 mg/L average interstitial pore water concentrations, we assumed a 100-fold safety factor to account for dilution. Thus, the nutrients added to each of the 10 designated reservoirs consisted of 2 kg of technical grade sodium nitrate (330 g of nitrogen) and 128 g of sodium tripolyphosphate ($Na_5P_3O_{10}$), which is more soluble in seawater than orthophosphate. The nutrients were added to seawater in the appropriate reservoirs and dissolved by recirculating immediately prior to application to the plots. Once a week, 30 L of a suspended mixed population of hydrocarbon-degrading bacteria was also added to the inoculum plots (see below).

The sprinkler system used for supplying the nutrients consisted of Schedule-40 PVC pipe (3.8 cm i.d.) connected to six Maxi-Bird impact sprinkler heads per plot (Rainbird, Inc., Glendora, CA), each rated at 6 L/min. Electric pumps (rated at 70 L/min) were connected to the PVC sprinkler manifold via 15 m × 1.9 cm diameter garden hoses. Seawater was applied to all plots regardless of whether they received nutrients, inoculum, or no amendment at all.

Inoculum Preparation. The indigenous inoculum was grown for 2 weeks in two 210-L stainless steel drums. To allow weekly inoculation with fresh 2-week cultures, each drum was offset in time from the other by 1 week. The drums contained 170 L of seawater from Delaware Bay, the weathered Bonny Light crude oil (600 mL) as the sole carbon source, and the same nutrients used on the beach. The original culture consisted of a mixed consortium isolated from the same beach several months prior to the experiment and grown on the same Bonny Light crude oil. The organisms were not characterized as to genus and species. The number of alkane and aromatic degraders measured in the drums were 1.9×10^5/mL and 2.5×10^4/mL, respectively. The oil in the drums became emulsified within 1 day following each inoculation, signifying actively metabolizing cultures.

Sample Size, Frequency, and Handling. Sand samples were collected every 14 days from the 15 oiled plots. Each plot was divided into four equal sectors (labeled α, β, γ, and δ, landward to seaward, respectively). Subsamples were collected from each sector to determine if differences existed in oil biodegradation according to the length of time under water. Two subsamples from each sector were collected according to a predetermined random number sequence that disallowed subsequent resampling from the same hole, composited into one sample, frozen, and shipped to Cincinnati for extraction and analysis by GC/MS. Thus, 60 samples, stratified within plots according to location within the intertidal zone and spread among 15 independent plots, were collected at each sampling event.

The subsamples consisted of two cores, each 7 cm in diameter × 14 cm deep, from one hole and two identical cores from another hole from the same plot sector. The samples were composited and mixed by a trowel in a galvanized bucket and placed in a prelabeled 3.8-L paint can. After the composited samples were thoroughly mixed, subsamples were taken from the mixture for other types of analyses (microbiological and toxicological). A portion of each composited sample was frozen and archived in the event that a re-analysis was needed at a later time.

Microbiological Analysis. Subsamples from each sector of each plot, including the five unoiled plots (80 samples altogether), were placed in Whirlpak bags, brought back under ice to the on-site mobile laboratory trailer, and immediately processed for most probable number (MPN) analysis of alkane- and PAH-degrading bacteria (*25*). Approximately 10 g wet weight (exact weight was recorded after weighing on a top-loading balance) was placed in a dilution bottle containing 90 mL of sterile detachment solution (1 g/L disodium pyrophosphate and 20 g/L NaCl) and shaken for 1 h at 300 rpm. The samples were then placed onto a Beckman Biomek 1000 Laboratory Workstation for automated serial 10-fold dilutions in 96-well microtiter MPN plates. The growth medium was Bushnell-Haas (*26*) supplemented with 2% sodium chloride.

Oil Chemistry. Frozen sand samples from the field were shipped to Cincinnati for processing. Either 100 or 500 g of sand was mixed with an equal volume of anhydrous Na_2SO_4. This mixture was extracted by sonicating three times for 10 min each with 150 or 450 mL of dichloromethane (DCM), respectively. This extract was poured through a funnel packed with anhydrous Na_2SO_4 into a tared round-bottom flask. The extract was then concentrated to dryness with a rotary evaporator. The flask was reweighed to determine the total DCM-extractable organic material (EOM). The residue was redissolved in DCM and diluted to a volume based on the amount of oil present. The final DCM extract was then solvent-exchanged to hexane. A 1.0-μL aliquot of the hexane extract was injected into a Hewlett-Packard 5890 Series II gas chromatograph equipped with an HP 5971A mass selective detector (MSD). The MSD was operated in the selected ion monitoring (SIM) mode for quantifying specific saturated hydrocarbons, polynuclear aromatic hydrocarbons (PAHs), and sulfur heterocyclic constituents.

The GC was equipped with a DB-5 open tubular column (30 m long, 0.25 mm i.d., and 0.25 μm film thickness) and a split/splitless injection port operating in the splitless mode. Operating conditions for the GC were as follows: injection port, 290 °C; transfer line, 320 °C; initial GC oven temperature, 55 °C held for 3 min; first temperature ramp rate, 5 °C/min to 280 °C, held for 5 min; second temperature ramp rate, 3 °C/min to 310 °C, held for 10 min. The total run time was 73 min. All analyte data were normalized to the conservative, nonbiodegradable biomarker C_{30}-17α-(*H*),21β(*H*)-hopane (*27*, *28*).

Nutrient Analysis. Concentrations of nitrate-N in the interstitial pore water of oiled plots were measured each day by collecting a sand core from each of the four sectors of a randomly selected test plot and the longitudinal midpoint of a nonnutrient control plot [to prevent interference with samples for oil analysis, the nutrient samples were all collected at the edges of the plots (i.e., within 30 cm of the boom)]. Each of the five samples was extracted with 1.0 L of deionized water on a shaker (the water had been previously acidified by adding 1.0 mL of concentrated H_2SO_4 to 500 mL of deionized water). Nitrate concentrations were quantified on an autoanalyzer after the pH was neutralized to 7.0 with 10 N NaOH. The method used was

based on cadmium reduction of nitrate to nitrite (*29*). Results were reported as milligram of nitrate-N/liter of interstitial water after determining the water content of the sample gravimetrically.

Laboratory Analysis of Biodegradation. To determine the rate of biodegradation of oil components in closed laboratory flasks for comparison to field observations, 500-mL respirometer flasks (*30*) were partially filled with 250 mL of artificial seawater, 5.0 g/L weathered crude oil was added to each flask, and the reactors were inoculated with a mixed culture of oil-degrading bacteria isolated previously from Slaughter Beach, DE, which is located about 1 mi north of the Fowler Beach area. The flasks were sacrificed periodically, and the entire contents was extracted with DCM followed by solvent exchange into hexane for GC/MS analysis of the PAH components of the oil.

Statistical Analysis and First-Order Hopane-Normalized Biodegradation Model. Oil constituents can be lost from a beach by physical washout, dissolution, volatilization, and biodegradation. An underlying assumption of this work is that a nonbiodegradable constituent of oil (namely, hopane) can be used to estimate the first three loss rate mechanisms and that the actual biodegradation rate of an analyte can be estimated from the difference between its total loss rate and its physical loss rate as estimated from the hopane loss rate. For this assumption to be true, the physical washout rate of the oil must be dominant, and the individual physical loss removal mechanisms of dissolution and volatilization must be negligible. Furthermore, due to the lack of more information about the mechanism of biodegradation of each analyte, the rate of biodegradation is assumed to be first order. Based on the aforementioned assumptions, the total loss rate of an analyte, $((dA/dt)_t$, the total loss rate of hopane, $(dH/dt)_t$, and the biodegradation rate of the analyte, $-kA$, are related by the following equation:

$$\left(\frac{dA}{dt}\right)_t - \frac{A}{H}\left(\frac{dH}{dt}\right)_t = -kA \qquad (1)$$

where A is the concentration of an analyte, H is the concentration of hopane, and k is the first-order biodegradation rate constant for an analyte. Using the definition of the derivative of a quotient, eq 1 can be rewritten as

$$\frac{d\left(\frac{A}{H}\right)}{dt} = -k\left(\frac{A}{H}\right) \qquad (2)$$

Integrating eq 2 yields the following first-order relationship:

$$\left(\frac{A}{H}\right) = \left(\frac{A}{H}\right)_0 e^{-kt} \qquad (3)$$

where (A/H) is the time-varying hopane-normalized concentration of an analyte, and $(A/H)_0$ is the value of that quantity at time$_0$.

Nonlinear regression analysis was used to estimate the first order rate of oil biodegradation for each of the three treatments and for comparison of the treatments. The coefficients of determination (r^2), which were derived from all the data (i.e., five replicates per sampling event × eight sampling events), were determined by the adjustment method of Kvalseth (*31*). Rate coefficients and intercepts of the three treatments were compared for statistical differences. Statistically valid variability estimates and power curves were obtained to aid the design of future bioremediation studies.

Results

Visual Observations. The crude oil was applied at low tide on the morning of July 1, 1994. The application was quite uniform, as the coarse sand absorbed the oil almost instantly as it was applied. The waves were mildly rough during the first high tide several hours later as winds picked up from the southeast. Waves breaking on the plots caused some oil to be lifted over the containment booms, and visible sheens were observed floating on the water. The sorbent booms were slightly discolored by the escaped oil. The amount of oil that actually escaped, however, was negligible. The mean concentration of total petroleum hydrocarbons (gravimetric residue weight) in samples collected from all 15 plots 4 days after application was 4.74 g/kg, which is within 5% of the amount of oil (5.0 g/kg) originally calculated to be applied.

During the course of the experiment, significant movement of sand took place within the plots due to tide and wave action. This was especially evident at the periphery of the plots because of the damming effect caused by the skirted containment booms. The three steel fence posts driven in the middle of each plot along with the steel posts retaining the boom that fell on the same transect served as a means of measuring the resultant change in topography.

Physical Loss of Oil. To distinguish physical loss from biodegradative loss of oil, the concentration of hopane in the sand was quantified in each sample. The measured overall means and standard deviations of the hopane concentrations at T_0, (i.e., the day nutrients and inoculum were first applied) according to position within the intertidal zone were α-sector, 3.58 ± 1.82 mg/kg; β-sector, 3.73 ± 1.56 mg/kg; γ-sector, 2.90 ± 1.05 mg/kg; and δ-sector, 1.38 ± 1.05 mg/kg. Knowing that the concentration of hopane in Bonny Light crude oil was 597 ng/mg oil (from GC/MS analysis), we computed the theoretical hopane concentration in the sand at T_0 to be 2.83 mg/kg sand (assuming that we sampled the entire oiled depth). This agrees well with the measured overall mean hopane concentration, which was 2.90 ± 1.07 mg/kg (averaged over all sectors). Note that the hopane concentrations were higher in the α- and β-sectors of the plots and lower in the δ-sector. This was caused by the breaking waves churning the oiled beach matrix and carrying it landward, which is typical of the oil deposition pattern in an actual spill event (*20*, *21*).

Figure 2a summarizes the overall disappearance of hopane with time from each of the three oiled treatments. The data, which were averaged over all intertidal sectors, represent plot mean hopane losses. First-order nonlinear regression curves for each treatment were fitted to the data, and no differences in rate coefficients or y-intercepts were found. Thus, an overall first-order curve was plotted through the pooled data, and a hopane half-life of 28 days was calculated. This was interpreted to represent physical loss of crude oil due to wave action and tidal inundation, since hopane was assumed to be nonbiodegradable in the time period of this experiment (*1*, *27*, *28*, *32*). Figure 2b is a similar plot showing the temporal loss of total extractable organic material from the plots. The half-life was 20 days. The EOM first-order rate coefficient was significantly higher than the hopane disappearance rate. The difference in loss rates (and half-lives) between hopane and EOM is attributed to biodegradation because EOM includes both

TABLE 1

Summary of Nitrate Concentrations by Block (mg of Nitrate-N/L of Interstitial Water)

	control		nutrients		inoculum	
block	mean	SD	mean	SD	mean	SD
1	0.7	0.7	3.9	1.4	2.6	2.3
2	0.8	0.9	9.5	3.3	3.9	3.2
3	1.3	1.1	6.2	3.8	1.1	0.5
4	0.6	0.5	3.6	2.1	5.5	5.5
5	0.8	1.3	8.6	7.9	4.2	2.4
total	0.8	0.3	6.4	2.7	3.5	1.7

biodegradable and nonbiodegradable components. However, EOM is not a sensitive enough indicator to discern treatment differences.

Nutrient Persistence. Table 1 summarizes the daily nitrate data from the oiled plots by block. The control plots receiving only seawater with no nutrients had measurable concentrations of nitrate (mean of 0.82 mg/L), which were approximately half the 1.5 mg/L target level desired for maximum biodegradation. The concentrations in the nutrient and inoculum treated plots were substantially higher. The Fowler Beach area of Delaware Bay was close to farm land, where runoff could easily account for the high background levels found. Samples along the shoreline of Delaware Bay were collected late in the project at considerable distances south and north of our experimental location and even in the Chesapeake Bay area, and the same high nitrate levels were measured. High nutrient levels are common in this coastal area (*38*).

Microbiological Analysis. Figure 3 summarizes the results of the alkane and aromatic degrader population data for all sampling events. No statistically significant differences were evident among the three oiled treatments at any sampling event. The populations in all the oiled plots were significantly higher than the unoiled plots. Even though the treatment differences were not statistically significant, the populations in the nutrient-amended plots were always greater than the nonamended (oiled) controls by about half an order or magnitude, especially in the latter weeks of the study. Note that the populations of alkane and aromatic degraders in the oiled plots were 2 orders of magnitude higher than those in the unoiled controls at T_0, which was 4 days after oil was applied. This suggests that considerable and rapid increases in the microbial populations occurred within 4 days due solely to exposure to crude oil and the natural background levels of nutrients present. The number of alkane degraders in both unoiled and oiled plots slowly decreased over time, while aromatic degraders increased almost 3 orders of magnitude in the first 2 weeks, leveled off, and then decreased. The aromatic degraders even increased in the unoiled plots, suggesting that enough oil may have initially escaped from the oiled plots onto the unoiled plots to cause a stimulation in growth. Note, however, that the amount of oil required to stimulate growth to approximately 1000 PAH degraders/g of dry sand is extremely low (<1 g of oil/plot) relative to the amount of oil added to each of the oiled plots (approximately 110 kg of oil/plot). One plausible explanation that could account for the observed lack of change in the alkane degrader populations was that they were already at their maximum field capacity at T_0.

Total Target Analytes. Results from the biweekly samplings are summarized in Figure 4a,b which shows the hopane-normalized concentrations of total target alkanes (i.e., the sum of all alkane analytes from *n*-C_{10} to *n*-C_{35} plus pristane and phytane) (Figure 4a) and total target aromatics (i.e., the sum of all groups of PAHs and sulfur heterocyclics analyzable by GC/MS and their alkyl-substituted homologues) (Figure 4b) in the nutrient-treated, inoculum-treated, and control plots as a function of time. Each data

TABLE 2

Summary of Rate Coefficients, *Y*-Intercepts, and Coefficients of Determination for the Total Analyte Biodegradation Data

	alkanes			aromatics		
treatment	intercept	k, day^{-1}	r^2	intercept	k, day^{-1}	r^2
control	171.1	−0.026	0.879	17.4	−0.021	0.839
nutrients	161.8	−0.056[a]	0.901	17.3	−0.031[a]	0.886
inoculum	163.0	−0.045[a]	0.911	17.9	−0.026[a]	0.829

[a] Rate coefficient significantly different from control ($p < 0.05$).

point is the mean of five independent replicates, and the error bars represent one standard deviation unit. The *y*-intercepts of the three treatments were not significantly different but the first-order rate coefficients were. Both the alkane and the aromatic biodegradation rates in the nutrient- and inoculum-treated plots were significantly greater than the control. Table 2 summarizes the intercepts, rate coefficients, and coefficients of determination (r^2) for the first-order relationships.

Individual Analytes. Figure 5 summarizes for each of the treatments the first-order biodegradation rate constants of individual alkanes calculated by nonlinear regression. The estimated initial concentrations (*y*-intercepts) were equivalent for all treatments, but the first-order rate coefficients were significantly different among the treatments for all of the analytes. The hopane-normalized loss rates in the nutrient- and inoculum-treated plots were significantly greater than the unamended controls. Hopane-normalized rate constants for nutrient plots averaged approximately 2.3-fold higher than control plots for normal alkanes and about 1.6-fold higher for the isoprenoid hydrocarbons. The latter result was expected, since branched alkanes are known to be more resistant to biodegradation than their straight-chain counterparts (*33*). Rate differences were somewhat lower for the inoculum and control plot comparisons, the inoculum plots yielding about 1.8-fold higher rate constants than the control plots for normal alkanes and 1.5-fold higher for the isoprenoids.

Figure 6 summarizes the comparative hopane-normalized first-order biodegradation rate constants of the individual PAH groups. Figure 6a compares the nutrient plots to the controls, while Figure 6b compares the inoculum plots to the controls. The rate constants for the nutrient-treated plots were significantly higher than the control for 16 of the 27 PAHs measured, whereas the rate constants for the inoculum-treated plots were higher for only 4 of the 27 compounds. The overall patterns of decay for all treatments were indicative of biologically mediated degradation reactions (*34*, *35*), i.e., the rate constants were higher for all parent compounds except pyrene and chrysene and progressively lower as more alkyl groups appeared on the ring structure. Rate constants for the parent and monomethylated naphthalene group were equal to or even greater than those of the lowest molecular weight alkanes in the nutrient-treated plots. Rate constants for the three-ring polycyclics were approximately equivalent to those of the intermediate carbon number alkanes in the unamended control plots or the high carbon number alkanes of the nutrient-treated plots. The naphthobenzothiophenes had the highest rate constants among the four-ring PAH groups. Concentrations of the pyrene and chrysene groups in this particular crude oil were close to the detection limit of the instrument, so calculated biodegradation rate constants are less accurate than for other compounds.

Table 3 compares the first-order biodegradation rate constants of the hopane-normalized two- and three-ring PAH compounds measured in the field to the rate constants measured in sealed laboratory respirometer flasks. Also shown in Table 3 are the rates of the hopane-normalized

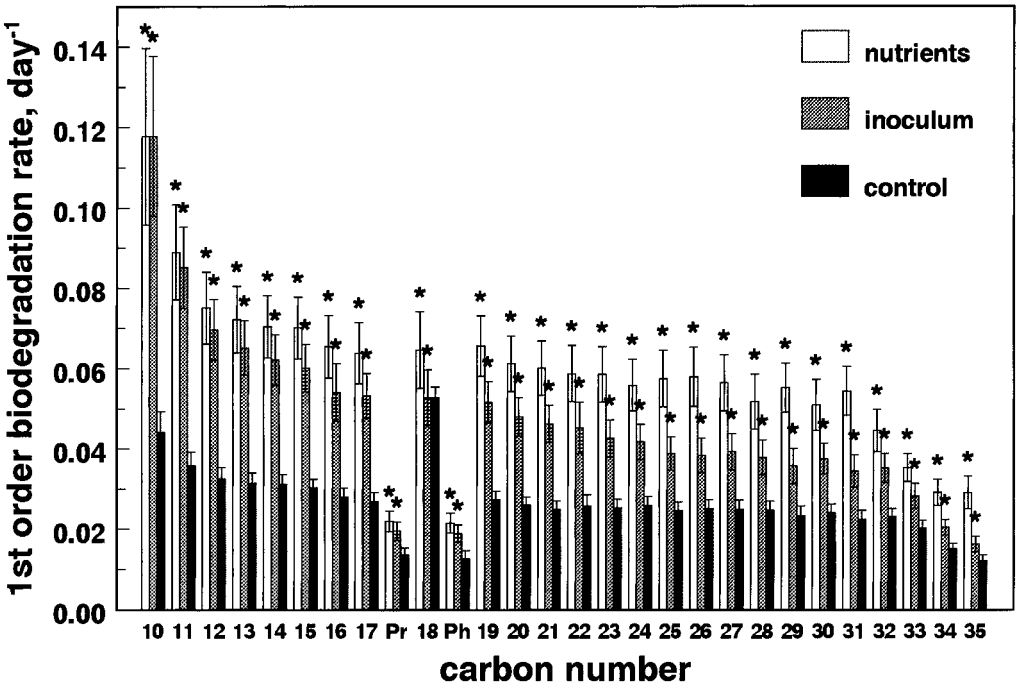

FIGURE 5. First-order biodegradation rates of all individual normal and branched alkanes computed by nonlinear regression of the data over the entire 14-week experimental time period [error bars represent ± one standard deviation unit, and asterisks identify significant differences from untreated control plots ($p < 0.05$)].

parent and substituted homologous PAHs relative to their respective highest and least volatile substituted homologue. For all compounds except naphthalene and C1-naphthalene, the agreement in biodegradation rates of the substituted homologues relative to their respective highest substituted homologue was nearly identical between laboratory and field, i.e., ratios ranged from 0.83 to 1.09 (last column, Table 3). The reason why the agreement broke down for naphthalene and C1-naphthalene was that the latter compounds are significantly more volatile than the others; consequently, rate constants of these two compounds were greater in the field. These results verify our interpretation that the pattern of loss of homologous PAHs measured in this field study are indicative of biodegradation as opposed to mere physical loss or solubility differences. Losses measured in the field represent losses due to washout, dissolution, volatilization, and biodegradation, whereas losses measured in a sealed flask can only be biodegradative. Since the relative rates measured in the field closely approximated those measured in the laboratory, differences in the dissolution and volatilization rates among homologues were negligible relative to differences in the biodegradation rates. Hopane normalization, which accounts for losses due primarily to washout, eliminates the uncertainty caused by all the physical factors acting on the oil components.

Positional Effects within the Intertidal Zone. Figure 7 summarizes the hopane-normalized first-order rate constants of the three treatments as a function of the plot sectors (i.e., α, β, γ, and δ) from which the samples were taken. The greatest differences between treated and control plots for both the saturate and the aromatic fractions of the oil were evident in the α-sector of the plots, i.e., the location closest to the high dune area of the beach. Somewhat lower rates occurred in the β-, γ-, and δ-sectors. These data suggest that more biodegradation occurred in the upper intertidal zone than in the lower intertidal area. This upper area of the beach is submerged the least and is thus likely to be exposed to higher aerobic conditions for a longer time period. It is also less subject to churning action of breaking waves, which occurs more on the lower portion of the beach. Thus, nutrients added for bioremediation purposes would persist longer in the higher intertidal zone and would be more available for continued biostimulation. To provide further support for this conclusion, we estimated the average time of submersion for each sector from available tide tables. The α-sector was under water for approximately 0.5 h/day, the β-sector for 2.5 h/day, the γ-sector for 6.5 h/day, and the δ-sector for 11 h/day. Submersion times were estimated independently for each tidal cycle. These time estimates begin when the tide reached the midpoint of each sector on the rising tide and when it reached the same point on the subsequent falling tide. These submersion times are based on average tidal elevations to the midpoints of the four sectors and represent the average time of submersion from rising tide to falling tide.

Statistical Power Analysis. A statistical power test was performed to determine the number of replicates that would be needed in future studies where the investigator wished to determine differences among treatments, given similar experimental conditions and variability as experienced in this study. Figure 8a presents power curves for the saturate fraction (similar power curves, not shown due to space limitations, were generated for the aromatic fraction) for a varying sample size (number of replicate plots) and a constant variance (σ). Figure 8b presents similar power curves for a constant sample size but varying σ. For a power of 80% (i.e., the probability that significant differences between two or more treatments are detected when indeed they exist), the difference in hopane-normalized alkanes between treated and untreated plots at any sampling time would have to be >120 at two replicates, 63 at three replicates, 47 at four replicates, 39 at five replicates, 31 at seven replicates, and 25 at 10 replicates to be statistically detectable at the variance experienced (Figure 8a). Actual

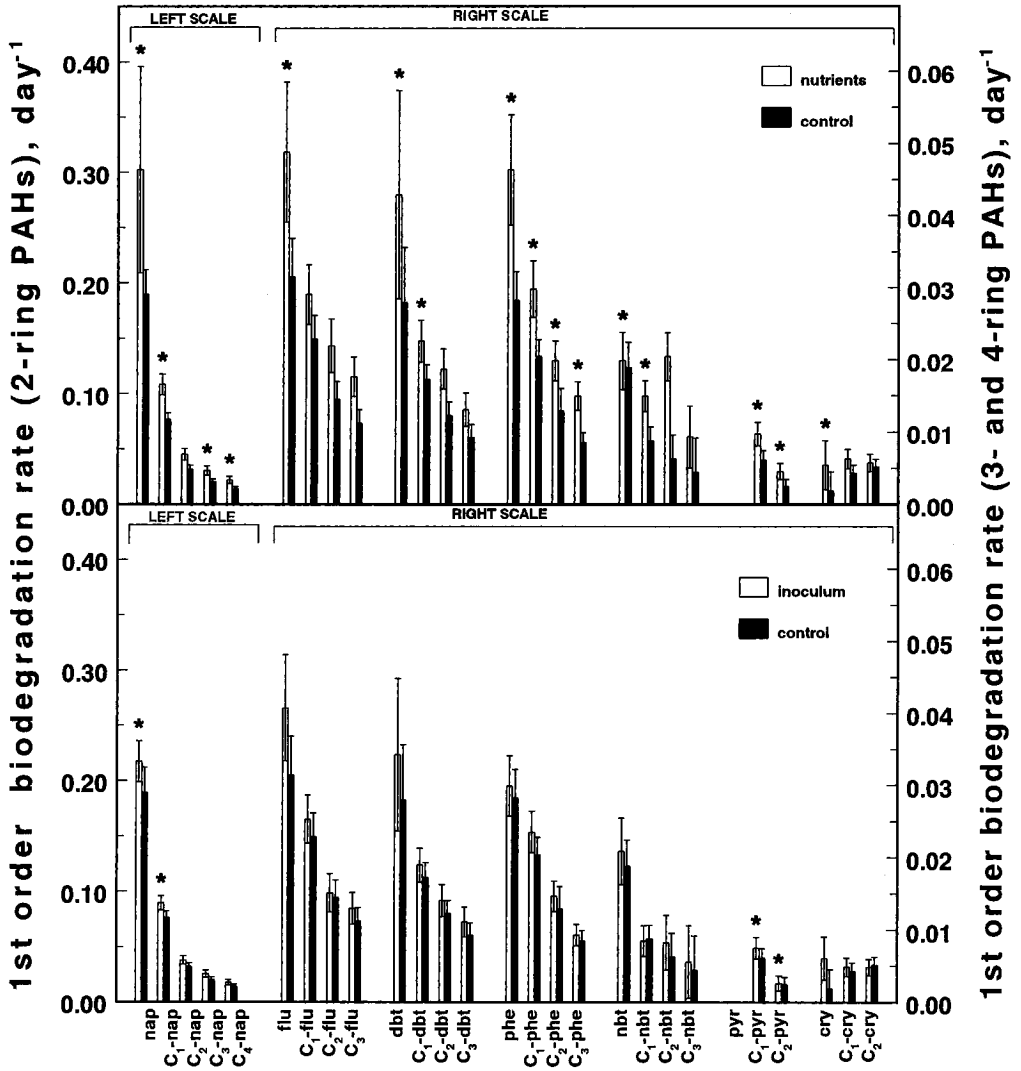

FIGURE 6. First-order biodegradation rates of all aromatics and their alkyl-substituted homologues. (a) Comparison of nutrient and control plots; (b) comparison of inoculum and control plots [error bars represent ± one standard deviation unit, and asterisks identify significant differences from untreated control plots ($p < 0.05$)].

observed differences averaged over weeks 4, 6, and 8 were 41 ng of alkanes/ng of hopane. Had only four replicate plots been used, the difference of 41 ng of alkanes/ng of hopane between the nutrient-treated plots and the control plots would not have been detectable. If the difference had been greater than 63 at any of those sampling events (i.e., due to a lower intrinsic biodegradation rate), we would have been able to detect such a treatment difference with as little as three replicates of each treatment.

For a power of 80% with a constant number of replicate plots (five), the difference in hopane-normalized alkanes between treated and untreated plots would have to be 20 at a variance of 8.3, 39 at a variance of 16.3 (the actual variance encountered in this study), 61 at a variance of 25.3, and 85 at a variance of 35.3 to be statistically detectable. Thus, if the expected variance in a future field study is 50% higher than that encountered in Delaware, a difference of 61 ng of alkanes/ng of hopane would have to exist to be statistically detectable with five replicates.

Topographical Changes. The plot-averaged change in elevation of beach sand relative to initial sand elevations determined at the time of the initiation of the experiment was computed for every sampling event. This calculation was performed along a transect bisecting the plot perpendicular to the water edge. Each plot had three internal posts and two edge posts along the transect. Depth measurements from the top of a post to the surface sand elevation were used for the calculations. The plot-averaged change in elevation was calculated from the changes in elevations measured along the posts using the trapezoidal rule according to the equation:

$$\Delta h = \frac{1}{\sum_{i=1}^{4} \Delta x_i} \sum_{i=1}^{4} (\Delta h_i + \Delta h_{i+1}) \frac{\Delta x_i}{2}$$

where Δh is the plot-averaged change in elevation (cm); Δh_i is the change in elevation at post$_i$ (cm); and Δx_i is the distance between post$_i$ and post$_{i+1}$ (cm).

These Δh data computed by the above procedure indicate very little change in average plot elevation over time: the average change was 1.1 ± 2.9 cm for the oiled control plots, 0.4 ± 2.5 cm for the nutrient plots, −2.4 ± 2.3 cm for the plots receiving both nutrients and inoculum, and −3.4 ± 4.6 cm for the unoiled control plots. It is clear from these data that little net sand movement occurred between the plots and the surrounding beach. Further-

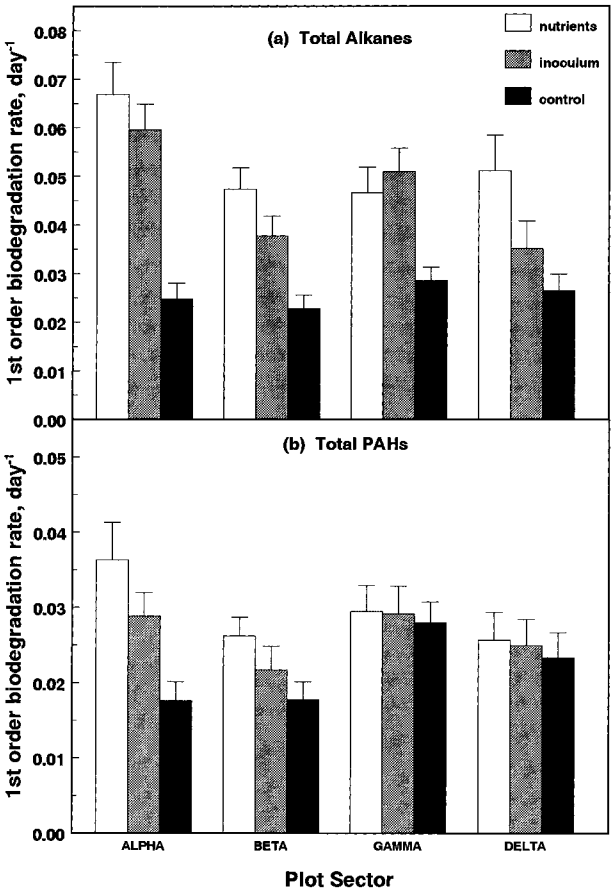

FIGURE 7. First-order biodegradation rates of (a) total target alkanes and (b) total target aromatics according to location within the intertidal zone (α-sector is closest to the high dune area; δ-sector is closest to the water) (error bars represent $\pm$ one standard deviation unit).

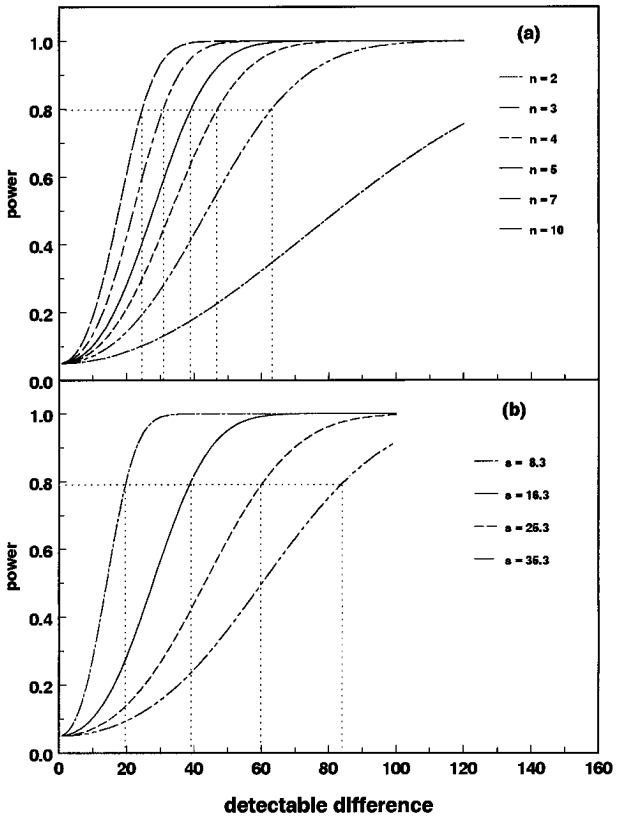

FIGURE 8. Statistical power curves for hopane-normalized total alkanes (a) for varying *n* and constant σ of 16.3 and (b) for varying σ and constant *n* of 5.

more, no meaningful difference existed between the boomed plots and the unboomed, unoiled plots relative to net changes in sand elevation. Although no net change in elevation occurred in the unboomed portions of the beach, we observed considerable movement of sand with rising and falling tides throughout the experimental period. This type of dynamic sand movement is exactly what would happen with oiled sand in a real spill where the whole beach is contaminated. However, in the latter instance, sand movement will not result in a major change in oil concentration in any one location because the whole beach is oiled. The fact that the boomed plots were able to retain the oiled sand for the duration of the study implies that results observed from this bioremediation study should closely simulate results expected from a study where the entire beach is oiled.

Discussion

In designing bioremediation experiments on a sandy beach, one has to contend with the fact that sand is transported into, out of, and along a beach by several mechanisms. Some of the mechanisms responsible for the movement of sand are tidal action, wind action, long-shore currents, animal and human activity, and storms. Since our permit limited the application of oil to 4×9 m plots, any movement of sand might have resulted in oiled sand leaving and fresh sand entering the plot. If the whole beach were contaminated, this movement of sand would not result in any major experimental problems since both the sand entering and leaving the plot would be contaminated; however, when only the plots are contaminated, any movement of sand will result in artificially accelerated dilution of the oiled sand. The use of hopane as a biomarker provides a procedure for overcoming this problem so that losses due to biodegradation can be isolated. However, dilution may result in toxicity reduction for which hopane normalization cannot account.

The two previously reported studies, which used replication and randomization to support the demonstration that significant treatment effects occurred, were conducted in terrestrial environments rather than on marine beaches (*15*, *16*). However, the abiotic loss mechanisms that act upon both the petroleum substrate and the nutrient amendments are substantially different in a beach environment as compared to a soil environment. The intertidal zones of beaches have much higher inputs of energy and flow-through of materials. The huge influx of seawater from tidal inundation can bring about substantial losses of hydrocarbons due to dilution. Surface waves as well as the interaction of tides and underground water flow are extremely important transport mechanisms for nutrients and bacteria and will affect the ability of exogenously introduced microorganisms to survive and colonize successfully. Consequently, the experimental design in a beach remediation field study is critical for providing the information needed to support objective conclusions on treatment effects. A randomized complete block design is ideally suited to test the biostimulation/bioaugmentation hypothesis.

Results presented in this paper were derived from five independent replicates of three separate and distinct oiled treatments. The reason why randomization was so im-

portant was to enable inferences on treatment effects over the whole experimental plane, not just the plots of interest. If a researcher has conducted a pseudoreplicate experiment and has assumed that no other effects except a treatment effect are present, then the inference will be limited to just the two plots of beach used in the experiment rather than the whole beach area, since a random sample of the plots, not the whole beach, was used. This has been the case in the vast majority of field studies reported (*1*, *2*, *8*−*11*, *13*). In this study, we did not want to limit our conclusions to the experimental plots; rather, we wanted to be able to infer treatment effects over the entire beach. The only way to accomplish this objectively was to sample randomly over the whole beach or a representative section of it.

The information from the statistical power analyses is useful for designing future research experiments involving three treatments in a randomized block design. If an experimenter has good reason to assume a certain variance and an expected treatment difference after a specified time period, the power curves from Figure 8 can be used as an aid in designing the experiment.

Clearly, bioremediation of crude oil spilled on a sandy beach in the temperate climate of the east coast can take place extremely rapidly. The nitrogen concentrations naturally present along the coast of Delaware Bay were high enough to sustain rapid intrinsic rates of biodegradation without human intervention. Although biostimulation with an exogenous source of inorganic mineral nutrients did indeed significantly accelerate the rate of hydrocarbon biodegradation, the incremental increase in biodegradation rate over the intrinsic rate (i.e., slightly greater than 2-fold for the alkanes and 50% for the PAHs) (Table 2) might not have been high enough to warrant a recommendation to actively initiate a major, perhaps costly bioremediation action in the event of a large crude oil spill in that area. This finding suggests that, in the event of a catastrophic oil spill impacting a shoreline, the first task is to measure the natural nutrient concentrations in that environment to determine if they are already high enough to sustain significant intrinsic biodegradation. If they are high enough, the next task is to determine if such a nutrient loading is typical for that area and season (i.e., determine the impact of chronic runoff from nearby agricultural practices or pollution from an upstream wastewater treatment plant or industrial discharge). Continuously renewable concentrations approaching 1−2 mg of nitrogen/L of interstitial pore water should support near optimum hydrocarbon biodegradation activity. The decision to supplement natural nutrient levels with an exogenous source should be based on how high the natural levels are relative to this threshold. If we had conducted this study on a beach with a similar temperature regime but subtantially lower background levels of nitrogen and had encountered the same biodegradation rates in the nutrient-treated plots, the rate enhancement factor would have been considerable because the background rate would likely have been substantially lower than that observed. In such a case, the decision to implement bioremediation would be unambiguous.

With respect to bioaugmentation as a means of enhancing cleanup of an oil spill, results from this study suggest that supplementation of natural populations with indigenous cultures from the same site may not result in further enhancement over and above simple nutrient addition. This conclusion could be extended to include allochthonous sources of microorganisms because if indigenous cultures that are adapted to the environmental conditions of the site do not accelerate the degradation rates, organisms enriched from different environments, grown in the laboratory, and not acclimated to a particular climatic or geographical location should be even less able to compete with the natural populations. The reason for this is that hydrocarbon degraders are ubiquitous in nature (*36*), and when an oil spill occurs at a given site, the large influx of biodegradable carbon will cause an immediate response in the abundance of hydrocarbon-degrading populations (*37*). If nutrients are limiting, however, the rate of oil biodegradation will be less than optimal. Supplying nutrients will enhance the succession initiated by the spill, but supplying added microorganisms will not because they still lack the necessary nitrogen and phosphorus to support growth on the oil carbon.

Perhaps of even more importance are the factors that determine the carrying capacity for hydrocarbon degraders in a marine beach environment. The most important influence is likely the physical removal rate caused by scouring of biomass when breaking waves tumble sand grains. If that is the case and indigenous bacteria are present, then they can grow to the carrying capacity rapidly if sufficient nutrients are present. Adding exogenous hydrocarbon degraders cannot increase the population density because physical removal will control it. In the present study, if nutrient supplementation was sufficient to bring the background biodegradation rate to near its maximum, bioaugmenting the natural populations is unlikely to stimulate the rate further. Of course, this assumes that what we observed was very near the maximum biodegradation rate and that such a rate was determined by something other than the growth rate of hydrocarbon degraders (e.g., oxygen concentration, maximum bacterial population density, surface area available for attachment). If this is the case, then we cannot assume that bioaugmentation is always unnecessary. This study suggests that, in addition to surveying the background nutrient levels at a spill site, the background hydrocarbon-degrading populations should also be determined as part of the site assessment. These levels should then be compared to some standard to determine if bioaugmentation is necessary. Such a standard does not exist at this time, but future research that would define the carrying capacities of various environments and the mechanisms that control them could be fruitful in this regard.

The differences that we observed in the rates of disappearance of homologous PAHs cannot be explained by differences in solubility or volatility. The biodegradation rates observed in sealed respirometer flasks showed nearly identical relative disappearance rates to those observed in the field. This lends credence to our conclusion that the patterns that we observed in the field were indicative of biodegradation, because losses due to volatilization and dissolution cannot occur in a closed system. Normalizing all measured analyte concentrations to hopane markedly facilitates conclusions regarding analyte biodegradability in the field. One must assume that hopane does not biodegrade at rates approaching the other analytes and that hopane is subject to the same physical loss factors to which all other oil components are subject. Based on the experience of this and other studies (*1*, *27*, *28*, *32*), the first assumption is well justified. The second assumption, however, is less certain. Hopane, which is a saturated, high molecular weight alkane, behaves like one with respect to

physical/chemical loss mechanisms. Despite this weakness, hopane normalization is useful as a first approximation for monitoring the progress of biodegradation in the field. No truly universal surrogates are available, and the extreme biological recalcitrance of hopane places it among the most reliable of available biomarkers. Used in combination with biodegradability differences within homologous series, hopane normalization can provide strong evidence in support of a biological removal mechanism during remedial operations.

In summary, we have shown that significant intrinsic biodegradation of petroleum hydrocarbons can take place naturally if sufficient nutrients already exist in the impacted area. We have also demonstrated statistically significant rate enhancement even in the presence of an already high intrinsic rate by supplementing natural nutrient levels with inorganic mineral nutrients. We affirmed that the decision to apply nutrients and microorganisms should depend on the background concentrations available at the contaminated site. We have shown that bioaugmentation will likely not significantly contribute to cleanup of an oil spill. We have developed for the first time from field data first-order biodegradation rate constants for the resolvable normal and branched alkanes and the important two- and three-ring PAH groups (and at least one four-ring PAH group) present in light crude oil. We have shown that the relative biodegradation rates of homologous PAHs measured in the field are close to those measured in the laboratory, thus corroborating the rates as being due to biodegradation and not physical washout or solubility differences. We have confirmed the importance of hopane as a useful biomarker for tracking biodegradation success in the field. We have demonstrated that maintenance of a threshold concentration of about 1−2 mg of nitrate-N/L of interstitial pore water will permit close to maximum hydrocarbon bioremediation. We have shown that better hydrocarbon biodegradation takes place in the upper intertidal zone than in the lower intertidal zone. And, finally, we demonstrated that the experimental conditions imposed by the booms surrounding the plots did not diminish our ability to simulate the sand movement that takes place naturally on a beach from long-shore currents and tidal inundations.

Acknowledgments

We wish to acknowledge the support and cooperation of Mr. Bennett Anderson of the Delaware Department of Natural Resources and Environmental Control. We are grateful to the hard-working field crew for their efforts in conducting the daily operations of the study. They were Messrs. Martin De La Garza and John Knopp, New Mexico State University; Frank Vilar, Florida International University; Jonathon O. Sharpe, Princeton University; John Darcy, Pennsylvania State University; and Gregory Wilson, University of Cincinnati. We thank the Marine Spill Response Corporation for providing the containment booms for the beach plots and the Sun Oil Company for contributing the crude oil. We acknowledge the able assistance of Ms. Gail Thomas of the EPA's Office of Solid Waste and Emergency Response in facilitating the permit application. We are also deeply grateful for the cooperation and generosity of Mr. and Mrs. Frank Draper, who owned and contributed the parcel of land on Fowler Beach where the study was conducted; Mr. and Mrs. Bruce Blessing upon whose property we set up our research trailers; and Mr. Joseph O. Penuel, who owned the parcel of beach property providing access to the Draper site.

Human Health and Socioeconomic Effects

HUMAN HEALTH AND SOCIOECONOMIC EFFECTS OF THE DEEPWATER HORIZON OIL SPILL IN THE GULF OF MEXICO

By Paul A. Sandifer, Alesia Ferguson, Melissa L. Finucane, Melissa Partyka, Helena M. Solo-Gabriele, Ann Hayward Walker, Kateryna Wowk, Rex Caffey, and David Yoskowitz

In the wake of the Deepwater Horizon oil spill, hundreds of miles of floating barriers, known as boom, were anchored in place to prevent oil from stranding on the shore and to reduce impacts to sensitive areas such as marshes and bird nesting grounds, as well as areas valued for human use like this fishing spot north of Dauphin Island, Alabama. *Photo credit: US Navy Photo by Chief Mass Communication Specialist Joe Kane, Fleet Combat Camera Group Pacific (Released)*

ABSTRACT. The Deepwater Horizon (DWH) oil spill is the only declared Spill of National Significance in US history, and it significantly impacted the health of people and communities in the Gulf of Mexico region. These impacts amplified adverse effects of prior disasters and may compound those of future traumas. Studies, both to date and ongoing, show some negative mental and physical health outcomes associated with DWH in some spill workers, as well as some coastal residents in all Gulf States. The spill was also associated with negative effects in the living resources, tourism, and recreation sectors, at least in the short term. Compared with others, people dependent on these sectors reported more health and financial concerns. Consumer concerns about the safety and marketability of seafood persisted well after data demonstrated very low risk. Parents were concerned about possible exposures of children as they played on beaches, but this risk was found to be minor. Spill-related stress was an overarching factor associated with adverse health outcomes, and some residents reported greater stress from navigating the legal and claims processes following the spill than from the spill itself. Research revealed a serious lack of baseline health, environmental, and socioeconomic data against which to compare spill effects. This finding highlighted the need for ongoing observing systems to monitor health and socioeconomic parameters and establish continuous baselines of such information.

INTRODUCTION

The Deepwater Horizon (DWH) oil spill was the largest ever in United States (National Commission, 2011) and the only Spill of National Significance. However, large oil spills, defined by NOAA (2017) as exceeding 100,000 barrels (420,000 gal) of oil are relatively rare, and very large ones even more so. Between 1969 and 2017, only 44 large oil spills (45 including the long-leaking Taylor Energy wells in the Gulf of Mexico; Mason et al., 2019) have occurred in US waters (NOAA, 2017), with about one-third of these in the Gulf.

Although they are rare, large oil spills can adversely impact the health of responders, cleanup workers, and residents, and the public welfare of affected communities (Walker et al., in press; Figure 1). The DWH spill also resulted in deaths of 11 oil industry workers. Physical and mental health effects have been reported and are closely related in disaster contexts (Aguilera et al., 2010; Palinkas, 2015; Ohrnberger et al., 2017; H.J. Osofsky et al., 2018), in part because environmental contamination results in significant stress (Hallman and Wandersman, 1992). How people adapt to repeated exposure to stress depends on an array of psychological, sociodemographic, economic, social, physical, and other variables (McEwen, 2005; Norris et al., 2008). Inhabitants of the Gulf region are particularly susceptible to oil spill health impacts due to widespread, preexisting health disparities, continuing exposure to contaminants, and location in a disaster-prone region (Lichtveld et al., 2016; Slack et al., 2020). Not surprisingly, the DWH oil spill, like Hurricane Katrina and other disasters, "had its greatest impact among those with the least" (Abramson et al., 2010).

From its beginning, the Gulf of Mexico Research Initiative (GoMRI) recognized the need for human-focused as well as environmental impact research. It sponsored a public health workshop and broadly advertised a request for research proposals focused on human health effects. Although articles explicitly focused on human health comprised only a small portion of research publications supported by GoMRI funding, they present important findings (Eklund et al., 2019). Additional health-related research was supported via the US National Institute of Environmental Health Sciences (NIEHS), in part with BP funding, some of which is summarized here.

DWH impacts on individuals, families, groups, businesses, and communities were extensive, and they compounded negative effects of previous disasters such as Hurricane Katrina in the Gulf. In turn, these effects are likely to exacerbate traumas of subsequent disasters as well as ongoing threats from chemical pollution, oil seeps, and harmful algal blooms. In this article, we describe potential, perceived, and actual impacts, beginning with the people expected to be most exposed to toxic substances—the response and cleanup workers—followed by effects on those who resided in spill-affected areas, possible hazards to children at play on beaches, seafood contamination risks, and socioeconomic effects on the Gulf's iconic fisheries and tourism industries and communities. We conclude with a discussion of the need for a human health observing system in the Gulf and a list of major findings and critical research needs for the future.

HEALTH EFFECTS ON RESPONDERS AND CLEAN-UP WORKERS

Oil spill response and cleanup workers (hereafter referred to as workers) can be exposed to a variety of hazards, including the oil and its components, burning oil, dispersants, and cleaning agents, plus mixtures of oil, dispersants, and other chemicals. Other work stressors include high heat and humidity, musculoskeletal strain, long working hours, and financial (e.g., job loss) and psychological (e.g., depression, anxiety) effects.

Between 1970 and 2009, there were 458 tanker spills greater than 700 metric tonnes (approximately 222,500 gals) of oil (IOTPF, 2009); 38 of those spills affected human populations. Of those 38 spills, only eight that occurred between 1989 and 2007 were studied in some detail for human health effects (Kwok et al., 2017a): *Exxon Valdez* (US), *Braer* (UK), *Sea Empress* (UK), *Prestige* (Spain), *Tasman Spirit* (Pakistan), *Erika* (France), *Nadhodka* (Japan), and the *Hebei Spirit* (South Korea) (B.-M. Kim et al., 2009; Aguilera et al., 2010; Jung et al., 2013).

Response to the *Exxon Valdez* oil spill led to many changes in oil spill preparedness, training, response, and worker safety and health, including use of personal protective equipment (PPE) in the United States (OSHA, 2020) and globally. Most studies of human health effects occurred in non-US countries where many workers from the community as well as volunteers engaged in oil spill cleanup with little protective gear. Studies that included pre-disaster health data were generally small, had shorter follow-up periods, and primarily investigated acute health symptoms. Acute health impacts were studied for up to one year after oil spill exposure in workers and affected community members to assess anxiety and post-traumatic stress, eye and skin irritation, and respiratory tract consequences (Palinkas et al., 1993; Zock et al., 2007; Na et al., 2012). Several studies reported longer-term respiratory symptoms in workers responding to the *Hebei Spirit* (Gwack et al., 2012) and *Prestige* (Zock et al., 2012) oil spills.

Human health studies following the DWH spill, the largest of their kind in history, are ongoing. Two epidemiological studies examine effects on the health of workers: the NIEHS Gulf Long Term Follow-Up Study (GuLF STUDY; Kwok et al., 2017a) and the US Coast Guard (USCG) Deepwater Horizon Oil Spill Cohort study (Rusiecki et al., 2018). These study teams have collaborated, and both are assessing potential long-term effects, including cancer.

The GuLF STUDY is assessing a

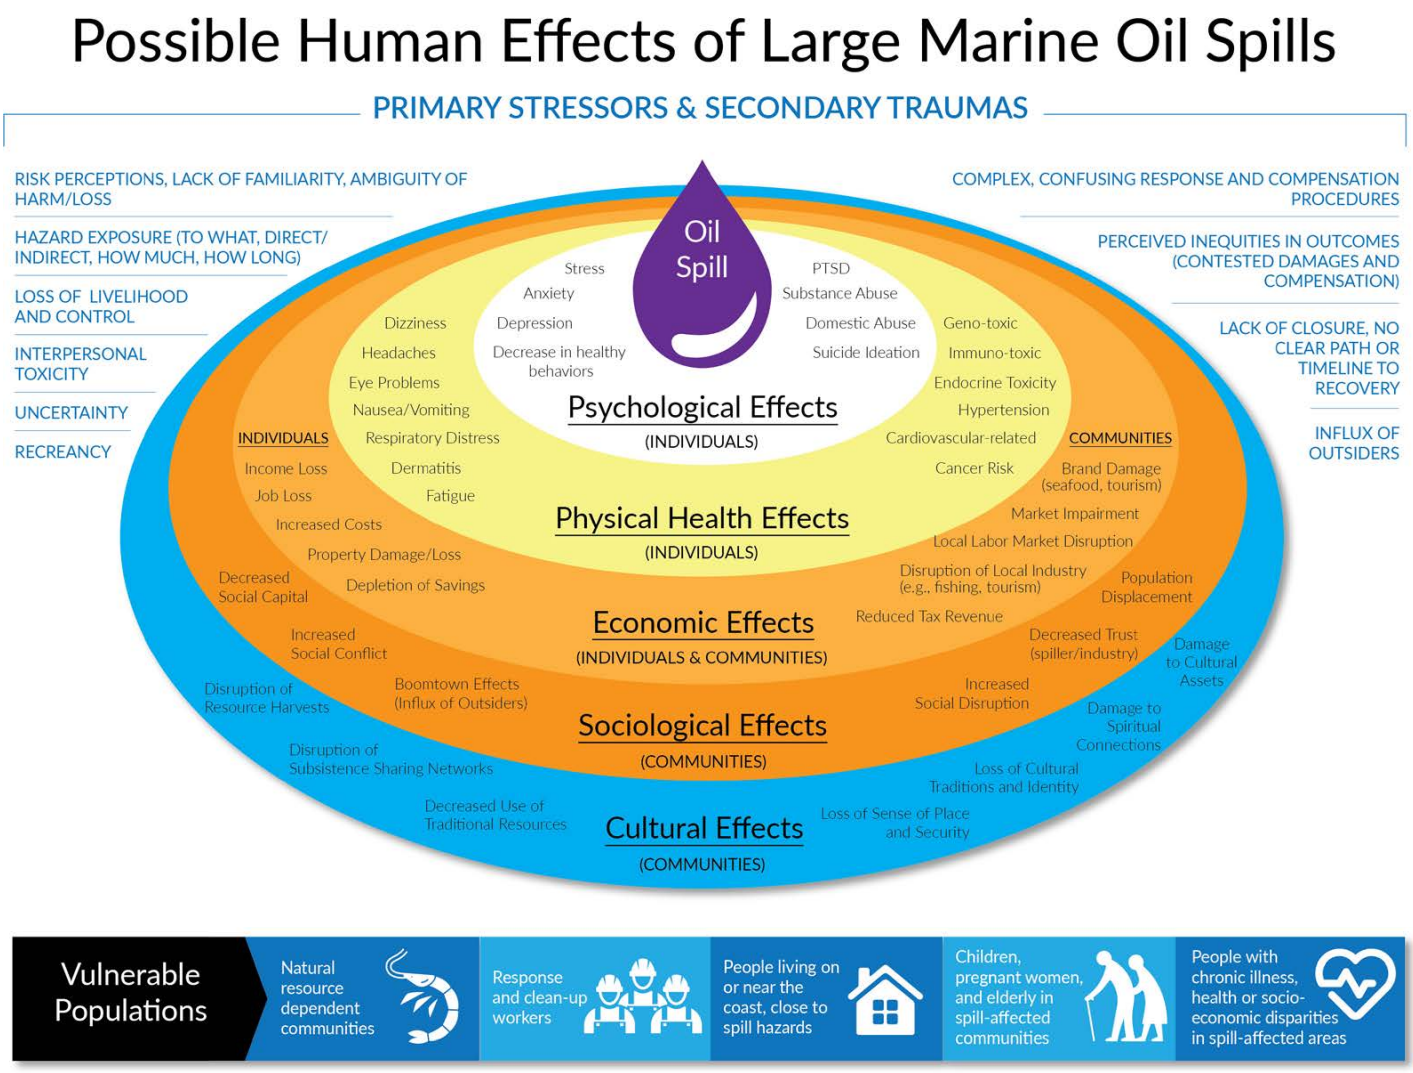

FIGURE 1. A summary of human effects research findings from studies on nine large oil spills: *Exxon Valdez* (USA), *Braer* (UK), *Sea Empress* (UK), *Prestige* (Spain), *Tasman Spirit* (Pakistan), *Erika* (France), *Nadhodka* (Japan), *Hebei Spirit* (South Korea), and Deepwater Horizon (USA). Relatively few spills have been shown to directly and adversely affect human mental and/or physical health, although many may have socioeconomic, ecological, or other effects of concern (Murphy et al., 2016). Whether any direct human effects occur from future spills will depend upon incident-specific conditions such as spilled oil type and volume, location, time of year, response actions, and safety and health protocols. Human susceptibilities to oil spill effects may be increased by pre-existing conditions, incident-specific and general life stressors, traumas, and previous disaster experience. Original concept developed by NASEM (2017) and adapted from Figure 3 in Beyer et al. (2016). Redrawn with permission from Sandifer and Walker (2018), with modifications.

range of human health effects, including worker access to mental health services (Lowe et al., 2015). It uses extensive data on actual and estimated exposures and health outcomes derived from surveys, home visits, and clinical records. Such limitations as self-reporting errors, confounding factors, and potential biases are documented in all papers and are frequently investigated with sensitivity analyses. The full cohort includes 32,608 people. Approximately 25,000 of these were actual workers, and the remainder were non-workers for comparison (i.e., people who were trained but not hired). The period of oil spill work activities was from April 20, 2010, through June 2011. Workers performed a variety of tasks with different exposure profiles under the primary categories of response, support operations, cleanup on water, decontamination, cleanup on land, and administration (Kwok et al., 2017a). The ultimate goal of the GuLF STUDY was to quantify exposures to total hydrocarbons (THC) and BTEX-H (benzene, toluene, ethylbenzene, xylene, hexane) via air measurements as a means of estimating potential toxic effects of THC and BTEX-H on workers (Kwok et al., 2017a).

The USCG cohort study consisted of 53,519 USCG personnel, 8,696 of whom responded to the spill and 44,823 who were not responders. The USCG study used health data from military medical encounters and cross-sectional survey data. Importantly, the USCG study can access a substantial amount of baseline health data for its participants, because medical data are available for all active-duty Coast Guard members from 2007 forward (Rusiecki et al., 2018). For the study, exposure levels and symptoms were based on self-reported and clinical data from the total cohort. While many health studies use self-reported information, including for toxic exposures, such data can be subject to recall and other biases (IOM, 1994; Williamson, 2007). Both the GuLF and USCG studies are continuing, with additional health effect papers expected.

Worker Exposures

To determine effects, physical health assessments evaluate elements of exposure pathways (ATSDR, 2005). THC and BTEX are generally considered to be the more toxic components of oil. THC is a composite of the volatile chemicals from the oil and was used as a surrogate for the workers' "oil experience." The exposure assessment used BP monitoring samples and agency short-term studies and accounted for oil changes due to weathering.

Kwok et al. (2017a), Rusiecki et al. (2018), and Ng et al. (2019) provided details of potential worker exposures and their measurements and estimations. Primary exposure pathways to the oil, burning oil (particulates), and oil spill chemicals are inhalation and direct contact (skin and eye). Due to the way offshore and onshore air quality measurements and exposure estimates were made, reported or observed symptoms cannot be linked to a specific crude oil chemical. From available data, it appears that total hydrocarbon exposure levels for workers likely were low compared to occupational standards (Middlebrook et al., 2012). However, an onshore study conducted from May 1 to September 30, 2010, assessed coastal ambient air quality for benzene and particulate concentrations ($PM_{2.5}$; Nance et al., 2016) using air monitoring data from the US Environmental Protection Agency (EPA) and BP. The EPA's Air Quality Index was compared prior to and during the spill. Onshore concentrations were generally higher following the spill, with benzene 2 to 19 times higher and $PM_{2.5}$ 10 to 45 times higher. Both concentrations were high enough to exceed public health criteria, with coastal areas near the spill and cleanup activities indicating measurable exposure disparities.

Worker Health Findings

GuLF STUDY findings to date have included nonfatal and fatal heart disease and reduced lung function in some workers. Reduced lung function has been documented in workers exposed to oily plants and wildlife compared to unexposed workers (Gam et al., 2018a). While Kwok et al. (2017b) linked reduced lung function with adverse mental health outcomes, Gam et al. (2018 a,b,c) found no association of depression and post-traumatic stress with lung function. Lawrence et al. (2020) reported improvements in lung function decrements four to six years after the spill, with those with the highest exposure exhibiting the greatest improvement.

When Strelitz et al. (2018) compared individual workers involved in DWH cleanup work with non-workers, they found a positive association between several oil spill related exposures and an increased risk of nonfatal heart attacks one to three years post spill. Factors associated with oil spill work, such as heat, strenuous conditions, physical exertion, and the health limitations of the individual worker, make it difficult to ascertain whether the risk of heart disease can be related directly to exposure to oil spill pollutants (Strelitz et al., 2019a). However, risk of heart disease has been associated with oil pollutants, cleanup activities, burned oil particulates, and volatile organic compounds (Strelitz et al., 2019b). The emotional stress related to the spill was also a possible cause of increased physical health risks such as heart attacks (Strelitz et al., 2018). Other analyses suggest that physical health symptoms contribute to cleanup workers' risk for mental health issues (Lowe, 2016). However, fishers who had longer periods of cleanup work and thus potentially higher work-related oil exposure also had higher income, which in turn is associated with lower anxiety and depression (Lowe et al., 2016).

The USCG study reported positive associations between exposure to crude oil, and in some cases oil and dispersant mixtures, and acute respiratory symptoms (Alexander et al., 2018); neurological symptoms including headache, lightheadedness, difficulty concentrating, numbness/tingling sensa-

tion, blurred vision, and memory loss/confusion (Krishnamurthy et al., 2019); heat stress (Erickson et al., 2018); and skin issues, as well as some gastrointestinal and genitourinary symptoms that have not previously been well evaluated (Rusiecki et al., 2018).

Dispersants

Dispersants warrant separate mention given the widespread public concern about their unprecedented use during DWH (Starbird et al., 2015; Kwok et al., 2017a). Although studied for decades by oil spill scientists, dispersants remain a controversial response option (Bostrom et al., 2015; Walker et al., 2018). Robust protocols for their application on the water surface were implemented during DWH (Houma ICP, 2010; ASTM, 2018), including monitoring for environmental effects and some air monitoring for 2-butoxyethanol, one of the components in Corexit EC9527A. Although 2-butoxyethanol had been removed from Corexit EC9500A as a result of health concerns related to the *Exxon Valdez* spill (NRC, 2005), it remained in Corexit EC9527A, which was used only in surface applications for about a month during the DWH spill (McGowan et al., 2017). Dispersants were also applied at the wellhead to mitigate impacts from surface oil slicks and to reduce levels of volatile organic compounds near the source. Because the measurements and support documentation related to the dispersants were insufficient to allow reliable estimation of exposure levels across the Gulf (Stewart et al., 2018), the GuLF STUDY used responses to survey questions to assess dispersant exposure and estimated that about 10% of its cohort could have been exposed to dispersants (Kwok et al., 2017a). Findings by McGowan et al. (2017) suggest associations between exposure to dispersants, specifically Corexit EC9527A or Corexit EC9500A, and acute adverse health effects (e.g., respiratory and eye irritation and chest tightness at the time of the oil spill work as well as symptoms that were present at the time of study enrollment one to three years after the spill). Although only 5% of the Coast Guard personnel who responded to the Deepwater Horizon Oil Spill Cohort study health questionnaire reported contact with both oil and dispersants, for example, through assignments to conduct Special Monitoring of Applied Oil Spill Technologies (Levine et al., 2011), self-reported adverse neurological health effects were worse for those workers than for those exposed only to oil, and heat exposure also exacerbated symptoms (Krishnamurthy et al., 2019). However, these authors cautioned that self-reported information can be subject to bias, and they did not have information about who was where and when in reference to possible exposures.

HEALTH EFFECTS ON NON-WORKERS

Human impacts of oil spills are much less studied than environmental impacts (Murphy et al., 2016), physical health effects are better researched among spill workers than in other populations (Laffon et al., 2016; Eklund et al., 2019), and mental health distress is better researched among community residents (Finucane et al., 2020a). Many, if not all, of the health effects noted for workers probably also apply to the general population that may be exposed, although the magnitude of the exposures may be considerably greater for workers.

Oil and associated chemical components have a wide range of known or putative toxic outcomes, including endocrine disrupting, carcinogenic, cytotoxic, immunotoxic, mutagenic, and genotoxic effects (Solomon and Janssen, 2010; Bhattacharya et al., 2016; Du et al., 2016; Laffon et al., 2016; Doctors for Environment Australia, 2019; Holme et al., 2019). Exposures can occur through physical contact with contaminants in air, water, or on materials; disruptions of routine behaviors; socioeconomic impacts; or other pathways (Hobfoll, 1991; Eisenberg and McKone, 1998; Slack et al., 2020).

Physical health problems or indicators identified with oil exposure include assorted respiratory issues; irritation of skin, eyes, nose, throat; chest pain; cardiovascular disease; gastrointestinal complaints; headaches, dizziness, fatigue, memory issues; and abnormal blood cell counts and liver and kidney function tests (e.g., Nance et al., 2016; Singleton et al., 2016; Afshar-Mohajer et al., 2018, 2019; Strelitz et al., 2019a). Laboratory experiments suggest that dispersant and dispersant-oil mixtures produce effects indicative of lung diseases such as asthma and chronic obstructive pulmonary disease (Liu et al., 2016) and mixtures may affect the gut microbiome (J.N. Kim et al., 2012).

Evidence for mental health distress associated with the DWH oil spill is mixed (Finucane et al., 2020a). Two large, population-based surveys in the Gulf Coast region suggest only modest or minimal changes in mental or behavioral health—at the aggregate level—before versus after the DWH spill (Gould et al., 2015). However, results across a range of other, more targeted studies indicate increased reports from individuals of symptoms consistent with depression, anxiety, and post-traumatic stress (Grattan et al., 2011; H.J. Osofsky et al., 2011, 2015; Buttke et al., 2012a,b; Gill et al. 2012, 2014; Morris et al., 2013; Drescher et al., 2014; Cherry et al., 2015; Fan et al., 2015; Aiena et al., 2016; Rung et al., 2016, Gaston et al., 2017; Kwok et al., 2017b). Substantial portions of coastal households (e.g., nearly 38% of an Alabama sample; Ritchie et al., 2018) were involved directly or indirectly in DWH-related claims, settlements, or litigation activity. Research on the compensation process suggests it was perceived by residents as random and lacking transparency, and resulted in additional psychological stress for individuals and corrosive effects on communities (Mayer et al, 2015; Ritchie et al., 2018; Halmo et al., 2019).

Even years after the spill, Gulf Coast residents report DWH-associated distress, but this may vary for different

social groups, in part because of differing prior trauma, life disruption (especially income loss), or available support (Arata et al., 2000; Grattan et al., 2011; Morris et al., 2013, Cherry et al., 2015; Rung et al., 2016; Ayer et al., 2019; Ramchand et al., 2019; Bell et al., 2020; Parks et al., 2020). Higher levels of social support, sense of community, and perceived resiliency seem to be protective against spill-related stress. However, social support was not ameliorative for all groups, such as those with high attachment to damaged resources (e.g., fishing households; Parks et al., 2020) or nonreligious people living in highly religious areas (Drakeford et al., 2019). Ayer et al. (2019) reported that, after controlling for other traumatic experiences, individuals with higher levels of DWH exposure were not at greater risk for behavioral health problems, except for illness anxiety.

Fishers and Seafood Workers

Fishers and seafood workers are often members of tight-knit cultural communities (Picou and Gill, 1996; Marshall et al., 2007), and the cultural identity of the Gulf Coast region is intertwined with fishing (Henry and Bankston, 2002). Short-term fishing moratoria were enacted immediately following DWH (see Seafood Safety section), and even when the moratoria were lifted, uncertainty about the contamination of fishing grounds continued for fishers and seafood workers (Simon-Friedt et al., 2016). In addition to pre-existing economic pressures (Harrison, 2020), the ongoing disruption and stress from the DWH spill contributed to the unique vulnerability of these workers (Gill et al., 2012; Lee and Blanchard, 2012; Cope et al., 2013, 2016; Parks et al., 2018). While greater social support is typically helpful in bolstering mental health, it may operate differently among renewable resource communities (Freudenburg, 1992; Gill et al., 2014). Indeed, Parks et al. (2020) found that fishing households with greater social support were more susceptible to depressive symptoms six years after the DWH oil spill.

Cope et al. (2013) evaluated suites of self-reported mental and physical health issues via the Louisiana Community Oil Spill Survey, conducted in spill-affected parishes in June 2010 while the DWH oil spill was ongoing, and again in October 2010 and April 2011. A physical health index was calculated based on responses to questions about how worries about the spill manifested as physical symptoms. The index was significantly higher (indicating more health concerns) among fishing households, and while the index declined in subsequent survey waves for those not involved in the fishing industry, it grew stronger over time for people in the industry. Parks et al. (2018) used the same data source to examine disruption of routine behaviors, including sleep, following the spill. On average, respondents reported difficulty with about one-third of the activities. Again, respondents with ties to the fishing industry were more likely than non-fishers to report disruption to routine behaviors.

Women, Pregnant Women, and Children

Results of previous studies revealing adverse reproductive health effects for people exposed to petroleum hydrocarbons led to concerns about potential impacts on pregnant women in the Gulf following the DWH spill (Merhi, 2010). In the case of the DWH event, women physically exposed to the spill or who experienced negative economic impacts reported physical symptoms such as wheezing or irritated eyes and nose (Peres et al., 2016). Similarly, pregnant women who lived near the *Hebei Spirit* spill site in South Korea reported more eye irritation, headaches, and pain than those further away (B.-M. Kim et al., 2009). With regard to reproductive health, Harville et al. (2018) found little evidence of DWH spill exposure being associated with increased miscarriages or infertility in women from southeastern Louisiana, although spills in Nigeria have been linked with increased mortality rates among newborn children (Bruederle and Hodler, 2019). Among patients (predominantly African American women) seeking care at a Federally Qualified Health Center in an underserved area affected by DWH, post-traumatic stress disorder was associated with headaches, chest pains, dizziness, or trouble sleeping (Langhinrichsen-Rohling et al., 2017). However, where patients received post-disaster, integrated health services, perceptions of personal resilience increased and negative physical symptoms decreased (H.J. Osofsky et al., 2018).

Children are especially vulnerable to oil spills due to their physiology (high respiratory and metabolic rates, developing immune and hormonal systems, small stature), behavior (e.g., inquisitive play; Tipre et al., 2017; Slack et al., 2020), and poorly developed ability to estimate risk (Fischhoff et al., 2010) (see section on Beach Exposures). Children exposed to the DWH oil spill were twice as likely to have mental and physical health problems compared to those who were not exposed, and African American children and those from low-income households had higher prevalence of health effects (Abramson et al., 2010). Based on health status reports for children four, six, and eight years after the spill, general health and numbers of recent physical health problems (respiratory symptoms, eye and/or vision issues, skin problems, headaches, or unusual bleeding) were worse in households that experienced physical exposure to the spill or job/economic losses (Slack et al., 2020).

PHYSICAL HEALTH EFFECTS TO POPULATIONS FOLLOWING BEACH CONTAMINATION: CHILDREN'S EXPOSURES AS AN EXAMPLE

Health-related exposures associated with oil spills can be estimated through quantitative risk assessment of health impacts. The risk assessment process addresses hazard identification (chemicals of concern and their environmental concentrations), exposure assessment (human activities that lead to exposure through

ingestion, skin contact, or inhalation), and dose-response evaluation (amounts of the chemicals likely to enter and be absorbed in the body (Figure 2; NRC, 2009; Ferguson et al., 2020a). The effect is an estimate of risk typically provided in units of probability.

Hazard Assessment

The first step in quantifying risks is to estimate the concentrations of oil spill chemicals within human exposure zones such as beaches. Thousands of chemicals can be found in crude oils. They can be broadly categorized into hydrocarbon, non-hydrocarbon, organometallic, and metallic compounds (Huba and Gardinali, 2016). Chemicals of concern in crude oil, those potentially toxic to humans, are the volatile aromatic hydrocarbons, BTEX-H, and the polycyclic aromatic hydrocarbons (PAHs) (ATSDR, 2005). Mitigation of oil spills can also include the use of dispersants, for which potential toxicities to humans are under debate (Ferguson et al., 2020a; NASEM, 2020; Quigg et al., 2021, in this issue); their use would need to be considered in risk assessments for future oil spills. Of the chemicals listed above, the PAHs and their degradation products have the most significant impacts at beaches because they weather slowly and are generally the most toxic (ATSDR, 2005). Also, toxicological profiles are not currently available for many oil chemicals and degradation products and for vulnerable populations for which information is very limited (e.g., pregnant women and children; Aeppli et al., 2012; White et al., 2016; Farrington, 2019).

Immediately after the DWH explosion, large-scale sampling efforts were initiated by the EPA, BP, and other organizations. Their measurements of oil spill chemicals were available within environmental matrices, including nearshore water and beach sediments, where beachgoers could be affected. Although these data provide snapshots of chemical concentrations, a more complete picture in time and space possibly could be obtained by using the data in oil spill models to predict oil spill chemical concentrations in nearshore environments. The General NOAA Operational Modeling Environment (GNOME) was used to help inform the Coast Guard-led response efforts about the areal extent of oil contamination. Initial efforts have been made to evaluate how well predictions from GNOME coincide with chemical concentration measurements (Montas et al., 2020; J. Xia et al., 2020, 2021), opening the possibility for future use of operational models to forecast oil spill chemical concentration distributions and provide an important first step for risk assessment.

Exposure Assessment

Different groups of humans can be exposed to oil spill chemicals at beaches, including response workers who actively engage in cleanup of contaminated shorelines and recreational users of these areas. Here, we focus on the recreational user category, and specifically on children who may be exposed to incidental residual oil that remains after beach cleaning and also to low level oiling that may occur from continuous leaks (e.g., Taylor Energy wells, seeps) and the redistribution of sunken oil. As noted elsewhere, children are a vulnerable constituency for exposures to contaminants in soil and sands, including potentially at beaches (Freeman et al., 2005; Xue et al., 2007; Beamer et al., 2012; Ferguson et al., 2019). In addition to factors noted previously, a child's mouth and nose are generally closer to the ground than an adult's, resulting in greater inhalation of pollutants that accumulate in sediments. Also, children's play habits involve intimate contact with and potential ingestion of beach sand (Shoaf et al., 2005), and they tend to dig, bury themselves, and sit in the very shallow water, which typically has the highest levels of contaminants (Shah et al., 2011; Wright et al., 2011). Although these behaviors are specific to the beach environment, they had not been quantified prior to research supported by GoMRI following the DWH. GoMRI-supported studies have quantified children's behaviors on beaches in Miami, Florida, and Galveston, Texas, through surveys (Ferguson et al., 2019), sand adherence studies (Ferguson et al., 2020b,c; Perone et al., 2020; Tomenchok et al., 2020), and videotaping of children and translating the videos to quantitative values that describe child beach play behavior (Alicia Ferguson, North Carolina Agricultural and Technical State University, *pers. comm.*, 2021). Collectively, these studies have documented child beach play behaviors that can now be utilized in risk assessment analyses.

Dose-Response Assessment

Effects from the uptake of chemicals are typically separated into two types: non-cancerous (acute and chronic) and cancerous. Non-cancerous effects are evaluated by comparing the estimated dose to minimum risk levels for chemical compounds. If the dose is greater than the corresponding minimum risk level, then non-cancerous illnesses are likely to occur. To estimate the probability of cancer, a slope factor is needed and can be obtained for some oil chemicals from

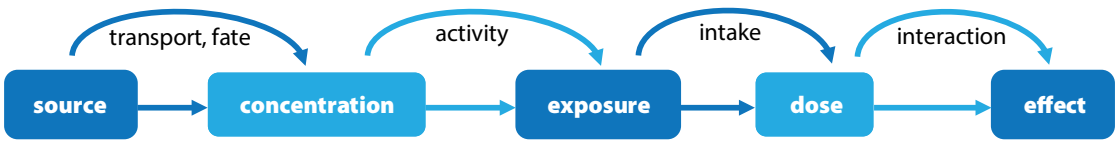

FIGURE 2. Framework for a risk assessment modeling platform.

toxicological profiles available through the US Center for Disease Control's (CDC's) Agency for Toxic Substances & Disease Registry and EPA's Integrated Risk Information System.

Risk Assessment Framework

Available information about hazard characterization, exposure assessment, and dose-response assessment has been incorporated in a risk assessment framework. Although work is currently ongoing to quantify children's activities, results to date indicate that children who play at beaches that were cleaned after oil contamination are unlikely to experience non-cancerous acute or chronic health effects. Additionally, increased cancer risks are very low, within the 10^{-6} order of magnitude (i.e., about one in a million; Black et al., 2016, Altomare et al., 2021), given toxicological information available at the time. Also, simultaneous exposure to multiple chemical contaminants was not compounded in the analysis. Moreover, mental health outcomes can manifest in physical outcomes from chemical exposures and were not integrated into the analysis.

SEAFOOD SAFETY

Oil Spills and Fisheries Closures

Following all oil spills in marine waters, the potential contamination of seafood supplies and the subsequent risks posed to human health from seafood consumption are of major concern to government authorities and community members where the spill occurred (Gohlke et al., 2011; Dickey and Huettel, 2016; Wickliffe et al., 2018). The magnitude and duration of the DWH spill posed a significant threat to the well-being of Gulf Coast communities, many of which depend upon safe and productive fisheries (Dickey and Huettel, 2016). At the time of the spill, Gulf fisheries accounted for around 16% of all US domestic landings (Shepard et al., 2013), fueling concerns of Gulf residents and non-residents about the safety of the nation's seafood supply.

In anticipation of potential contamination, surveillance testing of seafood around the periphery of the spill began on April 28, 2010. Just four days later, May 2, 2010, the first emergency fishery closure was announced. This was only the second time in US history that a fishery in federal waters was closed because of an oil spill (Fitzgerald and Gohlke, 2014). Shortly thereafter, on May 24, the federal government declared a fisheries disaster for the states of Alabama, Mississippi, Louisiana, and Florida (K. Xia et al., 2012). By early June, at the height of the spill, nearly 37% of federal waters in the Gulf of Mexico Exclusive Economic Zone were closed to fishing along with state waters extending from Louisiana to the panhandle of Florida and some public beaches (Ylitalo et al., 2012). Though federal fishing waters began to reopen as early as the end of June 2010, it was not until April 2011 that all federal waters, including those immediately surrounding the wellhead, were fully opened. Sampling of previously closed waters continued through June 2011 (Ylitalo et al. 2012). Although most fishery closures in state waters were lifted by August/September 2010, it was several more years before the most heavily impacted coastal waters in Louisiana were considered safe for fishing (Deepwater Horizon Natural Resource Damage Assessment Trustees, 2016).

Federal Response to Human Health Concerns

Higher molecular weight PAHs, like those that made up ~3.9% of the oil from the DWH well, are of particular concern for seafood safety because of their persistence in the environment, potential for uptake in aquatic species, and toxic or carcinogenic effects (Goldstein et al., 2011; Allan et al., 2012). Though the use of dispersants (Corexit 9500A and 9527) had been approved by the EPA, and they were determined to have minimal toxicity in laboratory experiments (Judson et al., 2010), their unprecedented use led to public concern about potential accumulation in seafood supplies (Ylitalo et al., 2012).

The federal response to seafood safety followed a similar approach to that used in the response to the *Exxon Valdez* spill in 1990, with minor modifications based on the difference in the nature of the Gulf oil and the environmental conditions in which the spill occurred (Ylitalo et al., 2012; Dickey and Huettel, 2016). Finfish and shellfish samples were collected from multiple seafood sources and at multiple locations and depths in areas free or cleared of oil (Ylitalo et al., 2012). Seafood samples were not collected from areas where oil was visibly present on the surface or chemically detected in the water column since these locations were closed to fishing (USFDA, 2010). Samples were screened for the presence and concentrations of 13 PAHs determined to have the most potential to harm consumers as well as dioctyl sodium sulfosuccinate (DOSS), an indicator compound for the dispersant Corexit 9500A. Levels of concern for each targeted compound were calculated based on a variety of factors that included estimated dose, mean adult body weight, and averaged seafood consumption rates for the 90th percentile of seafood consumers (USFDA, 2010). These levels were considered to be safe or associated with negligible cancer and non-cancer risk for the US population (Ylitalo et al., 2012). However, the risk level, estimated duration of exposure, and the use of national demographic values for body weight, consumption rate, and longevity were extensively scrutinized (Gohlke et al., 2011; Ylitalo et al., 2012; Wilson et al., 2015; Dickey and Huettel, 2016). There was particularly strong criticism around the adequacy of information about exposure risks and how those risks were communicated to vulnerable populations (Rotkin-Ellman et al., 2012; K. Xia et al., 2012; Sathiakumar et al., 2017), such as pregnant women and Vietnamese-American fishers and their families.

After nearly 10,000 samples and months of testing, federal and state authorities determined that Gulf seafood from reopened areas was safe for consumption (Ylitalo et al., 2012; Dickey and Huettel, 2016). While individual PAHs

of the 13 considered to be most harmful and/or carcinogenic were detected in many seafood samples, the concentrations were at least two orders of magnitude below levels of public health concern (Ylitalo et al., 2012). Further, DOSS was detected in less than 1% of samples and at very low concentrations. Though heavy metals were also a concern for many, particularly for vulnerable populations (Zilversmit et al., 2017), they were not included in the federal or state testing protocols (Fitzgerald and Gohlke, 2014). However, trace metal levels in both finfish and shellfish samples did not exceed background levels as determined by independent testing (Fitzgerald and Gohlke, 2014; Zilversmit et al., 2017).

Sathiakumar et al. (2017) specifically examined additional exposure risks to children from the coastal area of Mobile, Alabama, compared to children living inland. They concluded that there was no increased risk of exposure despite higher seafood consumption rates among coastal children compared to the general population. Further, Wickliffe et al. (2018) found that, even with consumption rates of both shrimp and finfish set at highly conservative values for human health (0.7 lbs [0.3 kg] per week and upward of 8.3 lbs [3.8 kg] per week, respectively), nearly three times the rates used to calculate the federal threshold levels of concern, concentrations in seafood samples did not constitute an unacceptable lifetime cancer risk.

Widespread fisheries closures following the DWH event reduced the probability of contaminated seafood entering into commerce. However, comparisons of pre- and post-spill consumption of seafood in multiple populations found a significant decrease in consumption in the immediate aftermath of the spill (Sathiakumar et al., 2017; Zilversmit et al., 2017; Wickliffe et al., 2018). Though the federal response to the spill, including the seafood testing program, drew much public scrutiny and concern, results from independent studies largely corroborated the federal effort. While some researchers found shortcomings in the federal approach, including the narrow scope of the PAHs included in chemical screening (Andersson and Achten, 2015; Dickey and Huettel, 2016; Farrington, 2019), based on toxicity information available at the time, no studies concluded that there was an excess exposure risk from consuming Gulf seafood in the months and years after the oil spill (Gohlke et al., 2011; Dickey and Huettel, 2016; Wickliffe et al., 2018). However, it is also largely agreed that the communication of exposure risks in general, and to vulnerable populations specifically, left much to be desired (Greiner et al., 2013; Dickey and Huettel, 2016).

SOCIOECONOMIC IMPACTS ON FISHERIES, TOURISM, AND COMMUNITIES

The DWH spill resulted in numerous socioeconomic impacts, including effects on the fishing, tourism, and transportation sectors, and others that may affect community vulnerability and resilience. Similar to investigations related to human health impacts, GoMRI supported research on DWH socioeconomic effects but at comparatively modest levels, with resulting publications constituting only approximately 6% of total GoMRI-funded publications and about 4.2% of total competitive grant funds awarded (Petrolia, 2014; Finucane et al., 2020a). While much progress has been made in longitudinal monitoring of biophysical parameters, there is a lack of similarly robust efforts to monitor a suite of socioeconomic variables that could be used to assess the value of non-market resources, or identify cultural attributes, attitudes, social connectivity, or resilience in an oil spill or other disaster context (NRC, 2013; Yoskowitz et al., 2015).

Economic Impacts

In an initial study, Sumaila et al. (2012) utilized input-output analysis to estimate economic impacts for commercial fishing, recreational fishing, and marine aquaculture. They projected the highest total economic losses to commercial and recreational fishing, US $4.9 billion and $3.5 billion, respectively. The largest commercial fisher losses were predicted for shrimpers, which accounted for almost 85% of the study's projected impact to that sector. In a separate analysis, Asche et al. (2012) suggested that, due to market integration, any increase in prices (driven by spill-related reductions in supply) would not offset expected revenue losses to domestic shrimpers. Rather, imports of farmed shrimp would rapidly increase to satisfy demand, meaning that while consumers would be mostly unaffected, producers could face significant and additive supply shocks. Overall, such impacts were expected to result in significant loss of income to shrimpers, as well as in boat building or repair, restaurants, and other businesses.

Notably, analysis is still needed to confirm economic impacts to fisheries 10 years after the spill. For example, while studies alluded to significant impacts to US shrimpers, in 2011, the year following the DWH spill, the Gulf produced >216 million pounds (98 million kilograms) of heads-on shrimp at a commercial landings value of >US $421 million (NOAA, 2020), accounting for about 68% of US shrimp landings that year (NRC, 2013). For comparison, average Gulf shrimp landings for the period 1990–2009 were 236 million pounds (107 million kilograms), with a range of 181–290 million pounds/yr (82–132 million kilograms/yr). While evidence does show reduced demand and a decrease in seafood sales directly after the spill (McGill, 2011), it is not clear whether these effects persisted. For example, the total commercial landings value for all species in the Gulf (Texas, Louisiana, Mississippi, Alabama, and Florida West Coast) for the seven years following the spill (2011–2017) was US $6.8 billion (Consumer Price Index [CPI] adjusted), whereas landings for the seven years preceding the spill (2003–2009) had a total CPI adjusted value of US $5.9 billion (NOAA Fisheries data, CPI adjusted).

Using biophysical projections from the Atlantis ecosystem model (Ainsworth et al., 2018) with input-output analysis, Court et al. (2020) modeled total economic impacts for the 10 years following the spill for commercial fishing revenues and recreational fishing expenditures. Results indicate that, across both sectors, impacts could include losses totaling US $2.3 billion composed of $1.2 billion in gross regional product, $700 million in labor income, and $160 million each in federal and state tax revenues. However, more research is needed to reconcile modeled outputs and actual landings data, particularly for sectors anticipated to incur significant impacts such as the shrimping industry.

With nearly 223,000 km^2 of fishable waters and public beaches closed or showing oil spill advisories during the months-long spill event (Ylitalo et al., 2012), the tourism industry was also impacted. Misperception also contributed to tourism impacts, with one report demonstrating that the public was unaware of locations and extent of damage and believing Louisiana waterways to be closed when they remained open (MDRG, 2010). Of those surveyed, 44% believed the oil spill caused damages on par with Hurricane Katrina, and 29% of tourists canceled or postponed planned trips to Louisiana due to the spill (MDRG, 2010). Another study found that about US $147 million in tourism and recreation claims were paid between August 2010 and March 2012. While this amount only represented 2% of total claims, it spanned 23 different business types within the industry, including airlines, aquaria, entertainment, water sports, wildlife watching, and more. Claims for impacts to retail, sales, and services were about US $1.9 billion representing 31% of total claims, while those for food, beverage, and lodging amounted to US $1.6 billion and 26% of the total (Eastern Research Group, 2014). Analysis of claims across the Gulf further found significant impacts on resorts, charter fishing, and marinas/docks/ice houses, though hotels and restaurants were most impacted. Effects differed among the states, with Texas receiving a relatively small amount of paid claims, while individuals in Florida and Louisiana received US $340 million and $227 million, respectively, and businesses US $164 million and $88 million, respectively (Eastern Research Group, 2014). Though individuals and businesses clearly suffered economic losses, counties with over 1,000 employees in tourism experienced only temporary or no declines in tourism-related employment, followed by growth, though there were exceptions. For example, Hancock County, Mississippi, experienced a 7.7% decline in tourism employment compared to 2009 (Eastern Research Group, 2014).

An important finding is that consumer perception matters and is an important driver of economic impacts. A review of news articles and interviews found numerous inaccurate portrayals of conditions, with media sensationalism contributing to a perception that the entire Gulf coast was contaminated with oil (Eastern Research Group, 2014). To counter such misinformation in the future, Nelson et al. (2018) offer a spatially explicit approach for evaluating and visualizing risks to tourism or other economic sectors.

Other studies also lend insights for future research. In a case study of New Orleans, Porter (2011) argues that fishing and tourism should be viewed as a cluster of overlapping geographic space, knowledge, and impact, for example, with tourism concentrated on recreational fishing and the seafood culture. Such interdependence may limit opportunities for growth where risks of economic and environmental crisis persist, yet innovation could address some risks to external shocks. For example, a tourism subsector could focus on ecotourism and demonstrate how the city and ecosystem remained resilient to the DWH disaster, which could provide a new kind of growth (Porter, 2011). Researchers also investigated non-market impacts of the oil spill. Alvarez et al. (2014) used choice modeling to estimate compensation due to marine anglers from non-market value losses at a mean of US $585 million with a 95% confidence interval. Petrolia (2014) offers that perhaps the most prominent change for research resulting from the disaster was an expansion to an ecosystem services approach to damage assessment. The National Research Council (NRC, 2013) assessed oil spill impacts on the provisioning ecosystem service of seafood and fish-based products, as well as the cultural services provided through recreational fishing (among other case studies). Results suggested that, while fishery closures may have decreased landings in the immediate aftermath of the spill (McCrea-Strub et al., 2011; NRC, 2013), increased catch rates were later observed for a large group of regularly harvested species (Fodrie and Heck, 2011; NRC, 2013). However, impacts from the spill to fishery harvest may take years or even decades to materialize, particularly regarding cascading effects through marine food chains (NRC, 2013).

Community Resilience Impacts

Resilience is "the capacity of a system to absorb shocks and disturbance and still maintain function" (Berkes and Folke, 1998), or "the capacity of a social-ecological system to adapt to change through self-organization and learning" (Berkes et al., 2003). Finucane et al. (2020a) examined a set of adaptive capacities that may diminish impacts of an ecological disaster like the DWH, finding that although the spill resulted in differing economic impacts across fisheries, tourism, and oil and gas sectors with location, the aggregate impacts were primarily short term. However, at the household level, and particularly in poorer households, financial impacts were still being felt years later. Further, community well-being showed signals of distress related to the spill across multiple studies. Distress was expressed differently across different groups, with those tied to natural resources for their livelihoods exhibiting higher rates, including through an erosion of trust (Finucane et al., 2020a).

Similarly, Cope et al. (2016) found levels of distrust across communities regarding information provided by both BP and the federal government, with trust in state government being somewhat stable. Mayer et al. (2015) reported that, although the compensation process helped to mitigate economic impacts, apparent confusion, lack of transparency, and perceived inequality in the process eroded trust and strained community relations. In addition to those reliant on natural resources, other groups identified as having higher vulnerability to the spill included populations that exhibit disadvantages related to rural environment, dependence, older age, and socioeconomic and/or educational disparities, as well as living in mobile homes (Cope and Slack, 2017), being of minority ethnicity (e.g., Vietnamese; Patel et al. 2018), or being female (Lightfoot et al., 2020). In a case study of Apalachicola, place, heritage, and moral identity were found not to be fixed community attributes but rather to provide individuals with varying resources, which in turn impact disaster recovery (Clarke and Mayer, 2017). This has important implications for institutional recovery frameworks—often crafted by external actors—in a precarious Gulf region where resilience may vary locally. For future spills and other disasters, more attention should be given to the researcher-community relationship, where cultural norms and trust are critical for successful engagement with local residents (Lesen et al., 2019; Finucane, 2020b).

NEED FOR A COMMUNITY HEALTH OBSERVING SYSTEM

Environmental disasters of various kinds and magnitudes occur frequently in the Gulf region (NOAA, 2020; Sandifer et al., 2020; Smith, 2020), with one often following another and compounding the impacts of the previous incident. Examples include the 2010 DWH oil spill that followed the catastrophic effects of Hurricane Katrina in 2005, and the health effects of which were then compounded by subsequent disasters such as Hurricane Harvey in 2017, and others (J.D. Osofsky et al., 2014; Shultz et al., 2015; SAMHSA, 2018). Recurrent disasters take a heavy toll on human health in the region, where many people already suffer significant health and economic disparities (Lichtveld and Arosemena, 2014; Lichtveld et al., 2016). Climate change, land subsidence, and population and development pressures are all likely to increase the incidence and severity of environmental disasters in the Gulf region, along with their accompanying adverse effects on human health (Sandifer et al., 2020).

Previous studies of health effects of Gulf disasters, as well as other sections of this article, demonstrate the lack of, and critical need for, baseline health information with which to compare effects of future disasters (Sandifer et al., 2020). Ongoing health monitoring is essential to develop and maintain such a baseline and capture acute, chronic, and long-term health impacts, as well as secondary complicating events that occur in the intervals between major disasters. Recognizing the urgent need for a health observing system in the Gulf of Mexico region analogous to the kinds of atmospheric and oceanic observing systems well established for monitoring and predicting hurricanes and other extreme weather events, GoMRI commissioned a design study. The intent was to devise a framework that would provide for continuous collection of health information to ensure existence of adequate pre-, during, and post-disaster information for comparative purposes and to improve emergency planning and public health response. The resulting framework (Sandifer et al., 2020) builds upon and leverages existing ongoing national health surveys and includes new longitudinal cohort studies designed to elucidate long-term health trends and disaster-associated health effects in the five Gulf states. The system's new cohort studies must continue indefinitely, be large enough to represent the risk-prone coastal areas and populations known to be particularly vulnerable to disasters, and include mental and physical health assessments and measures of stress. In addition to collecting and providing information on direct and indirect health impacts to individuals, the system should also incorporate community data. As far as we are aware, this is the only observing system designed for a disaster-prone area and focused explicitly on disaster-related health effects.

Components of the proposed Gulf of Mexico Community Health Observing System would include: three cross-sectional surveys, the National Health and Nutrition Examination Survey (NHANES; https://www.cdc.gov/nchs/nhanes/), the Behavioral Risk Factor Surveillance Survey (BRFSS; https://www.cdc.gov/brfss/), and the National Health Interview Survey (NHIS; https://www.cdc.gov/nchs/nhis/); a proposed new Augmented BRFSS survey for the Gulf states; the new National Institutes of Health (NIH) All of Us national longitudinal study (https://allofus.nih.gov/); and proposed new Large, Small, and Disaster-Specific Gulf of Mexico longitudinal cohort studies (**Figure 3**). The cohort studies are designed to build upon one another and are the unique and most important parts of the observing system. Another significant strength of the system is its ability to adapt rapidly as needs arise and new biomedical and other technologies are developed.

The geographic focus of the proposed observing system is the 68 coastal counties of the five Gulf states. These are counties that either have a Gulf shoreline or are near the coast and contain Federal Emergency Management Agency (FEMA)-identified areas with high risk for tidal and/or storm surge flooding (Ache et al., 2013). A statistically representative sample of volunteers from the populations in these counties is proposed, with stratification to ensure proportionate inclusion of both urban and rural populations and with additional, targeted recruitment as necessary to enroll adequate numbers of people deemed par-

ticularly vulnerable or typically underrepresented (e.g., ethnic minorities, the underserved, and those who suffer health, health care, and economic disparities). Initially, volunteer participants are expected to be recruited using a mail-address sampling frame, followed by use of electronic communication means to the greatest extent possible.

If implemented, assessments of mental and physical health in the new cohort studies will include information obtained via detailed health questionnaires, clinical examinations, biological specimens, electronic health records, and use of wearable health devices. These will be augmented with data from secondary sources such as information from State Health Departments and the CDC, national community surveys, environmental exposure databases, social media, remote sensing, and others. Biomarker data derived from biological samples are expected to be used as indicators of health status, including for calculation of measures of chronic stress and its impacts on physical and mental health.

Primary users of information from the health observing system will be public health and medical professionals, emergency managers and responders, and clinical and academic researchers. Secondary users are likely to include political, community, and business leaders, and many others. Data and information products are expected to be used to assess disaster-related health effects; enhance disaster planning and response; improve protection for disaster responders and workers; build individual and community resilience; and promote new clinical, biomedical, and public health research and practice.

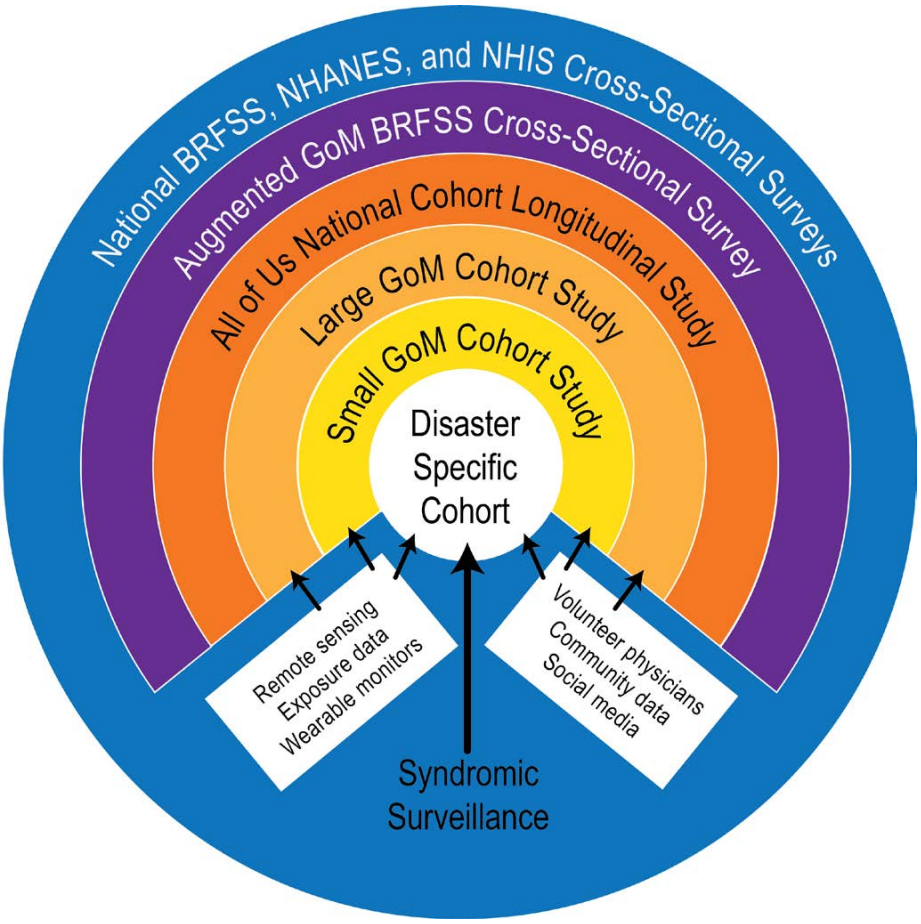

FIGURE 3. A conceptual framework for a Gulf of Mexico Community Health Observing System. *From Sandifer et al. (2020)*

CONCLUSIONS, GAPS, AND OPPORTUNITIES

A broad range of mental and physical health impacts has been attributed to oil spills in general and the DWH disaster in particular, but in most cases definitive cause-and-effect linkages are lacking. Overall, mental and physical health effects and their interactions are inadequately studied for oil spill workers, their families, and others who may be exposed to or affected by them. Besides spill workers, special attention is needed to vulnerable people, including individuals with chronic illness or who suffer health and health-care disparities and/or socioeconomic deprivations, lack strong social support, the elderly, and natural-resource-dependent communities.

A common theme across studies is the overarching role of stress (e.g., from physical exposure, job or income loss, compensation/litigation processes, or behavioral disruption) as an important factor associated with poor mental and physical health outcomes.

Human health findings were severely limited by a lack of baseline health data, long delays in implementing major health research activities following the spill, heavy reliance on self-reported and cross-sectional survey data, limited collection of clinical health information, and a paucity of long-term, longitudinal cohort studies. Health studies need to be initiated before, during, or immediately following a large spill and must continue long enough to identify long-term effects and secondary surges of chronic illnesses. Critically needed are cohort studies that start before a major spill and continue through it and onward for a long period after.

Considerable information about components of oil (e.g., benzene) and their potential toxicity to humans was available before the DWH spill, but many gaps in knowledge were identified, including effects of field-relevant exposures to oil components, engine exhaust, and other chemicals (e.g., dispersants and decontamination cleaners) as well as these in combination with additional stressors

such as heat and humidity. Recent studies indicate that children who played at beaches that were cleaned after oil contamination are at low risk for acute or chronic health effects. However, further development of models to forecast the distribution of fresh and weathered oil is needed to predict potential human exposures and inform the common response question, "How clean is clean enough?" Also, toxicological profiles are not currently available for many oil chemicals and degradation products and for vulnerable populations for which information is very limited (e.g., pregnant women and children). A better understanding is needed of impacts from exposures to multiple chemicals, and that incorporates mental health impacts from oil spills that contribute to adverse physical outcomes.

When fisheries were reopened following closures after the spill, Gulf seafood was demonstrated to be safe for human consumption within guidelines existing at the time. However, there was much uncertainty and persistent worry about seafood safety, even years after the spill. For future large spills that affect fishing zones, thorough and rapid appraisals of seafood safety should be undertaken immediately after the spills, followed by plain language communication regarding consumption risks based on appropriate demographic information (e.g., race/ethnicity, age, sex/gender identification, pregnancy, chronic illness, weight, seafood consumption habits), and there should be regular updates. Better health advisories targeted to vulnerable populations and those who use beaches and coastal recreation areas are needed. Collaboration between government and stakeholder groups for monitoring of seafood should be enhanced, and additional social science research should be supported to improve risk communication strategies and outcomes.

There is a lack of systematic collection and integration of socioeconomic data necessary to assess near- and long-term societal impacts of oil spills. Also lacking is a concerted effort to aggregate existing data, identify and fill gaps in longitudinal data collection, and make data and information products broadly available to enhance community disaster resiliency and recovery. As an example, even 10 years after the DWH spill, the long-term psychosocial impacts resulting from the extensive fisheries closures have yet to be fully understood, although extensive data have been collected.

Major Opportunities for the Future

Establishment of the proposed Gulf of Mexico Community Health Observing System would be a major step toward improving health care planning and response and in identifying and characterizing acute, chronic, and poorly known adverse health effects of oil spills and other disasters. The system could be modified for use in other disaster-prone regions.

To inform future oil spill response protocols, findings of worker-related health effects studies should be viewed in the context of oil spill response practices, including operationally relevant exposures, worker safety and health standards, and pollutant and dispersant monitoring protocols, perhaps facilitated by an expert workshop involving researchers, preparedness and response decision-makers, and the Occupational Safety and Health Administration (OSHA) (Holliday and Park, 1993; Science and Policy Associates, Inc., 1993).

There is an urgent need for and the opportunity to develop a socioeconomic observing system. Such a system would link the most significant available socioeconomic data streams, identify additional needed information and suggest how it should be collected, and aggregate the data so as to be useful in analytical efforts to accurately estimate social and economic impacts of future large spills.

DEDICATION. This article is dedicated to the memory of Ciro V. Sumaya, MD, MPHTM, founding Dean of the Texas A&M School of Public Health and a member of the GoMRI Research Board. It was he who, in 2013, convened the GoMRI Public Health Workshop, the report from which has helped to guide GoMRI's efforts ever since on the DWH explosion's and spill's effects on human health. We mourn his tragic death and miss him very much.

Annex II

ESA Consultations

Endangered Species Act &

Essential Fish Habitat

Post Response Guidance

Endangered Species Act (ESA) and Essential Fish Habitat (EFH)
Post-Response Procedures

The purpose of this document is to inform the Federal On-Scene Coordinator (FOSC) of the potential need to conduct consultations **after** the emergency response phase of an incident is over, though every effort should be made to engage the Services early on concerning potential or actual response actions. During the course of emergency response operations, an FOSC must document and track environmental compliance implementation procedures regarding ESA Section 7 and EFH including, but not limited to: Incident Command System (ICS) Form 232-CG Resources at Risk Summary reports, Incident Briefing Form (ICS 201), ESA/EFH Emergency Consultation checklists, etc. The FOSC must comply with consultation requirements for ESA Section 7 and EFH pursuant to 50 Code of Federal Regulations (CFR) § 402.05 and 50 CFR § 600.920.

During a response, the FOSC is responsible for directing response actions so that ESA listed species are not put at risk, or that formally designated Critical Habitats of ESA listed species and/or EFHs are not destroyed. This process is accomplished through pre-spill planning consultations, along with documenting the results of those consultations within Regional Contingency Plans and Area Contingency Plans, as appropriate. However, spill response remains incredibly dynamic and not all federal actions and impacts can be appropriately planned for. For actions not covered by a pre-spill consultation that are used, or are considered for use during an emergency response, the FOSC must follow ESA and/or EFH emergency response procedures and complete ESA and/or EFH consultations in collaboration with the Services once the emergency phase of the response has ended.

There are three criteria for evaluating the effects of response actions on ESA listed species and designated Critical Habitats, and two criteria for evaluating the effects of response actions on EFH. These criteria are used by the FOSC to determine the type of ESA consultation required with National Marine Fisheries Service (NMFS) and/or U.S. Fish and Wildlife Service (USFWS), and/or type of EFH consultation required with NMFS. Depending on the incident response, the FOSC may coordinate with the National Oceanic and Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC), Department of the Interior (DOI) representative, subject matter experts, and/or the Services to determine whether response actions had one of the following effects.

For ESA listed species and designated Critical Habitats:

(1) The action had **No Effect** (none at all, negative or positive);

(2) The action **May Affect**, but was **Not Likely to Adversely Affect (NLAA)**, listed species or adversely modify or destroy designated Critical Habitat; or

(3) The action **May Affect,** and was **Likely to Adversely Affect (LAA)**, listed species and likely adversely modified or destroyed designated Critical Habitat.

For EFH:

(1) The action had **No Adverse Effect**; or

(2) The action **May Adversely Affect** (**Adverse Effects** are anything that changes the quality or quantity of EFH).

"No effect" or "no adverse effect" is the appropriate determination if the response actions occurred in an area where no ESA listed species and designated Critical Habitats occur and no EFH is present, or

if the action and the stressors of that action would not affect ESA listed species, designated Critical Habitats, or EFH. To assist with "no effect" determinations, the FOSC should ask whether ESA listed species or designated Critical Habitats were exposed to the action or the effects of the action. If not, then "no effect" is the appropriate determination. For example, if there is a seasonality to the presence of an ESA listed species, and the action occurs within the season where the species is not present during the time of response actions, then a "no effect" determination is acceptable. An example of this is nesting loggerhead sea turtles in the Gulf of Mexico. If shoreline cleanup is to occur at the time when there are no nests and no nesting activity, then the action would have no effect on loggerheads. However, it is important to check whether other sea turtle species may be nesting in the area. This "no effect" determination must be documented within the respective unit's administrative record. Similarly, if the "no adverse effects" on EFH determination is made, this should also be documented.

If the FOSC determines that emergency response actions "may affect" ESA listed species and/or designated Critical Habitat—that is, species or designated Critical Habitats are likely to be exposed to the response actions—then the FOSC shall follow the consultation processes identified in 50 CFR § 402 during and following the emergency operations.

If the FOSC has made a "may affect" determination during an emergency response, the FOSC must engage in emergency consultation with USFWS and/or NMFS as soon as practicable. This engagement with the Services during the response will likely aid in reducing the likelihood of adverse effects on listed species and/or designated Critical Habitats and should help the FOSC meet their responsibility to engage in the post-response consultation once the response has ended. In accordance with the 2001 Memorandum of Agreement (MOA), these consultations shall remain active until the conclusion of emergency response operations.

Pursuant to 50 CFR § 402.14(c), the FOSC must submit a written request to the Services once the emergency response phase is over. The type of consultation and request to the Service(s) will depend upon the type of effects the response actions had on listed species and/or designated Critical Habitat. If the FOSC determines that the response actions were NLAA (***informal consultation***), the FOSC must then submit a letter to the Service(s) with the details below, their determination, and request concurrence on that NLAA determination. If the FOSC determines that the response actions were LAA, the FOSC must submit an initiation package (and/or Biological Evaluation) to begin ***formal consultation*** after the emergency phase of the response is over. This process is necessary to document and evaluate any adverse effects that may have occurred as a result of response actions. The FOSC cannot make a determination on jeopardy or adverse modification of critical habitat, this is the responsibility of the Services. Therefore, the FOSC must work with the Services to evaluate response actions determined LAA (by the FOSC), and if those response actions resulted in jeopardy or adverse modification of critical habitat. Due to the nature of emergency consultation, determinations of jeopardy or adverse modification of critical habitat are challenging to evaluate during a response. However, any recommendations provided by the Services during the response and the consultation, after the fact, must be documented in the resulting emergency BO and can be integrated into future response actions and response plans.

The following information must be provided to the Services in order to begin an informal or formal consultation:

(1) A description of the agency response action(s) taken;

(2) A description of the specific area that may have been affected by response actions to include listed species and designated Critical Habitat;

(3) A description of Best Management Practices (BMPs)[1] that were followed, if applicable;

(4) A description of the manner in which any ESA listed species or designated Critical Habitat may have been affected by the response action, and an analysis of any cumulative effect;

(5) Any relevant reports, including environmental impact statements, environmental assessments, or biological evaluations prepared, if applicable; and

(6) Any other relevant available information on the response action, listed species, or designated Critical Habitat.

Informal consultations conclude with a Letter of Concurrence from the Service(s). Formal consultations conclude with a Biological Opinion (BO) from the Service(s). For examples of template letters, BOs, or any additional ESA Section 7 templates or document, please refer to NRT.org[2]

RRT 3 Environmental BMPs for Coastal Zone Oil Spill Response

REGIONAL RESPONSE TEAM III (RRT3)

Environmental Best Management Practices (BMPs) for Oil Spill Response in Regional Response Team 3 (RRT3) Coastal Zone

Appendix 9-A6

December 2023.1

RECORD OF CHANGES

The Regional Response Team III (RRT3) Executive Committee approved the RRT3 Environmental Best Management Practices (BMPs) for Coastal Zone Oil Spill Response on December 6, 2023. Maintenance of this plan is the responsibility of the RRT3 Consultation, Natural Resources, and Damage Assessment (CNRDA) Workgroup. Minor changes may be made periodically, and an update and review will be conducted at least once per year, at a minimum, to validate points of contact. The most current version of the plan will be posted on the RRT3 Website under the Regional Contingency Plan (RCP) Appendix 9 and the USCG District 5 District Response Advisory Team (D5 DRAT) Sharepoint site.

USE OF THE ENVIRONMENTAL BMPS FOR OIL SPILL RESPONSE IN THE COASTAL ZONE

Regional Response Team III (RRT3) is committed to implementing measures to reduce and avoid potential impacts on federally listed and managed species, designated critical habitat, Essential Fish Habitat (EFH), and cultural/historical resources. The RRT3 has compiled the following collection of Best Management Practices (BMPs) to avoid and/or minimize impacts to trust resources under the Marine Mammal Protection Act (MMPA) and Migratory Bird Treaty Act (MBTA), to serve as recommendations under the Endangered Species Act (ESA) Section 7 consultation regulations to avoid and minimize effects to endangered and threatened species and critical habitat, to minimize and avoid adverse effects on identified categories of EFH under the Magnuson-Stevens Fishery Conservation and Management Act (MSA), and to avoid and minimize effects to cultural and historic resources under the National Historic Preservation Act (NHPA) Section 106.

Background and Purpose

The purpose of this document is to provide recommendations and guidance to the Federal On-Scene Coordinator (FOSC) to avoid and minimize impact to fish, wildlife, and cultural/historic resources during a response to an oil spill.

All BMPs are provided as recommendations and guidance, developed in coordination with Department of Commerce National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS), and U.S. Department of the Interior's (DOI) U.S. Fish and Wildlife Service (USFWS), to avoid and minimize impact to fish and wildlife resources during a response to an oil spill. These agencies are referred to as "the Services." State Historic Preservation Office (SHPO) input for cultural/historic resource considerations during oil spill response operations is also included within this guidance document.

This document is not intended to cover all possible scenarios or every individual species. The BMPs provided in this document are general in nature for oil spill response actions and enable the FOSC to quickly implement BMPs for response actions at the onset of a response. Due to area, environmental, and situational differences amongst potential operation areas, the RRT3 maintains this list of BMPs as an appendix to the Regional Contingency Plan and will update and revise the list as additional BMPs are developed, and/or updated information becomes available regarding the effectiveness and feasibility of implementing the BMPs. Incident specific BMPs may need to be developed to account for incident specific variances based on spilled products, species or location specific concerns, and types of response actions utilized and/or considered.

Direction to USCG Fifth District Units

The U.S. Coast Guard (USCG) Fifth District units will take these BMPs into consideration when carrying out oil spill response operations. This guidance will be used to cover oil spill and/or hazardous substance response actions within the Fifth Coast Guard District coastal zone, which includes Delaware, District of Colombia, Maryland, portions of New Jersey, North Carolina, portions of Pennsylvania, and Virginia.

The regional NOAA SSC and/or DOI Regional Environmental Officer **shall** be informed whenever the FOSC engages in emergency consultation with the Services. The SHPO **shall** be notified for NHPA consultations.

U. S. Coast Guard (USCG) District Incident Management and Preparedness Advisors (IMPAs) and District Response Advisory Teams (DRATs) are excellent resources to consult with regarding application of BMPs.

The USCG IMPA and DRAT are available 24/7 via District Command Centers.

Note: *This is a guidance document only. Units are encouraged to suggest modifications to this document to the RRT3's Consultation, Natural Resources, and Damage Assessment (CNRDA) Workgroup.*

ENVIRONMENTAL BMPS FOR COASTAL OIL SPILL RESPONSE

General Response Operations

☐ Response personnel may not attempt to scare, herd, disturb, or harass any protected species to encourage them to leave the area. Coordination with National Oceanic and Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC), U.S. Fish and Wildlife Service (USFWS) and/or National Marine Fisheries Service (NMFS) Stranding Coordinator, or appointed point of contact, may result in authorization for these actions.

☐ Report stranded, injured, sick, trapped, entangled, or dead wildlife to the Incident Commander (IC) and Environmental Unit as soon as possible to ensure appropriate agency notifications are made. *Utilize the 'USFWS Wildlife Spill Response Survey' within the Survey123 app if available and being utilized for incident* ArcGIS Survey123 Downloads (esri.com)*.The USFWS species are preloaded into the Wildlife Spill Response Survey, however any species including NMFS species can be recorded in the app.*

☐ If a sea turtle is stranded, injured, or sick, and actively moving, it should be retained onboard a vessel or if on land, responders should remain with the turtle until the stranding/rehabilitation personnel provide guidance on what action should be taken, which could include transferring the turtle to a designated stranding/rehabilitation facility.

☐ If a sea turtle is stranded, injured, or sick but unresponsive (doesn't move its head or flippers when handled), you should follow the handling and resuscitation guidelines after you have called the NOAA hotline at 866-755-NOAA (6622). Do not assume that an inactive turtle is dead. The onset of rigor mortis and/or rotting flesh are often the only definite indications that a turtle is dead. Releasing an unresponsive turtle into any amount of water may drown it. Unresponsive sea turtles may recover following resuscitation.

- For your and the turtle's safety, always pick it up by the shell and keep your hands away from the head. Sea turtles have been known to revive up to 24 hours after resuscitation procedures have been followed. In accordance with Sea Turtle Resuscitation Regulations (50 CFR 223.206(d)(1)), steps for resuscitation can be found at https://media.fisheries.noaa.gov/dam-migration/sea_turtle_handling_and_resuscitation_measures.pdf.

☐ Handling live sturgeon should be minimized and used only when necessary. Sturgeon should be supported by a sling or net when being moved. Live sturgeon must never be held vertically by the tail or gills and should never be tied by the tail. Sturgeon should be kept in water to the maximum extent possible to reduce stress.

- For a non-responsive or overly stressed sturgeon, personnel must allow the animal to recover in floating net pens or in well-aerated onboard live tanks and shielded from direct sunlight. Alternatively, the sturgeon may be immersed in clean river water and moved back and forth to aid water passage over the gills.
- The sturgeon should be released as soon as possible when it has recovered. At water temperatures <7°C (44°F) and >27°C (80°F), holding time of a recovered sturgeon must not be greater than 30 minutes. A spotter should watch the fish as it is released making sure it stays submerged and does not need additional recovery immediately after release.
- Sturgeon are extremely sensitive to chlorine and other sanitizing solutions. Use care when using any of these products around sturgeon.

☐ If any impacted sea turtle, sturgeon, or marine mammal (or their parts) are observed, NMFS should be contacted for collection protocols. If a Wildlife Branch is stood up, coordination for response and collection should be communicated through the NMFS representative in the Wildlife Branch. NMFS may authorize collection by spill response personnel if species specific responders are not available (and delegation authority is allowed under the appropriate permit) and will provide instructions on proper handling and disposition. For impacted marine mammals and sea turtles, call the NMFS Regional Marine Animal Hotline: 866-755-NOAA (6622), Option zero to speak with NMFS staff. For sturgeon, reports should be made to NMFS Protected Resources Division by phone (978-281-9328) and e-mail (nmfs.gar-sturgeon-salvage@noaa.gov) as soon as possible.

- Do not dispose of any federal trust resource marine mammal or turtle parts until examination and documentation is conducted. Disposal will not take place until federal trustees (NOAA/USFWS) give final approval.
- Wildlife operations present some unique challenges to evidence handling requirements that often must be resolved early in response. Important data and samples are collected during oil spill response that ultimately may be used to assess exposure of species to oil and injuries resulting from that exposure. This information and material ultimately may be used for legal purposes including both criminal and civil proceedings. The potential for litigation associated with an oil spill requires specific measures when collecting, handling, and transferring samples and data. Coordinate with federal trustees (NOAA General Counsel's Office and the DOI Office of the Solicitor) to ensure chain of custody (CoC) protocols are followed. The CoC record should include the names of sample collectors, sample identification numbers, date and time of sample collection, location of sample collection, and names and signatures of all persons handling the sample in the field and in the laboratory. The documents provided below provide chain of custody information:
    - Guidelines for Oil Spill Response and Natural Resource Damage Assessment: Sea Turtles at https://media.fisheries.noaa.gov/dam-migration/opr-61_final.pdf.
    - NOAA Pinniped and Cetacean Oil Spill Response Guidelines at https://repository.library.noaa.gov/view/noaa/10479.
    - Additional chain of custody forms for other NOAA resources can be found at https://www.diver.orr.noaa.gov/field-forms-and-templates.

☐ Human Safety Considerations:

- Prior planning, training, and protective equipment should be provided for responders that may need to engage directly with marine mammals.
- Zoonotic pathogens are another risk of handling marine mammals.
- Safety perimeters around pinniped colonies should be established.

Vessel Operations

☐ All response vessel operators and crew must watch for and avoid collision with species protected under the ESA and MMPA (sea turtles, manatees, seals, dolphins, whales, Atlantic and short-nose sturgeon). The Environmental Unit can provide an updated list of protected species in the response area. When available a dedicated wildlife observer should be assigned for each response area.

☐ All response vessels shall maintain minimum distances specified below for specific species:

- 1,500-ft distance (500 yards) from North Atlantic right whale.
- 300-ft, as practicable, from all other marine mammals (i.e., dolphins, other whales, seals/pinnipeds, and porpoises):
  - Seal colonies will likely flush (i.e., move away from) from haul outs into the water at greater distances than 300-ft. Consideration should be given to the potential presence of pups on haul outs in certain seasons. A biologist associated with an authorized marine mammal stranding response program experienced in marine mammal/protected species identification should be onboard to advise location of boom deployment distances when possible.
- 300-ft from waterfowl /seabird aggregation sites. Large numbers of sea birds and waterfowl winter in coastal waters bays and tributaries, with flocks of up to 5,000 individuals. Boat operations must maintain a minimum distance from waterfowl / sea bird aggregation sites.
- 150-ft from sea turtles.
- 50-ft from manatees (rare in RRT3). All in-water operations, including vessels, must be shut down if a manatee comes within 50 ft of the operation. Activities will not resume until the manatee(s) has moved beyond the 50-ft radius of the project operation, or until 30 minutes elapses if the manatee(s) has not reappeared within 50 ft of the operation. All on-site project personnel are responsible for observing water-related activities for the presence of manatees. Animals must not be herded away or harassed into leaving.
- 100-ft from all other protected species not already listed above. Stop operating mechanical equipment, including response vessels, immediately if any protected species is observed within a 100-ft radius and resume after the species has departed the area of its own volition.

☐ All response vessels should:

- If marine mammals, sea turtles, or bird colonies are observed within the response area, report to Environmental unit via Wildlife Hotline and/or USFWS Wildlife Spill Response Survey in Survey123 (if established). If Environmental Unit is not yet established, report to the Operations Section. If there is the potential for damage to marine resources, it is recommended that an Environmental Unit be established. Reports should be submitted by the end of the current operational period.
- When sea turtles, dolphins, or whales are sighted while the vessel is underway (e.g., bow-riding), attempt to remain parallel to the animal's course. Avoid excessive speed or abrupt changes in direction until they have left the area.
- Report if a whale is observed within the envelope of the NOAA spill trajectory for the next 48 hours.

- Any vessel collisions with and/or injury or impacts to any protected species (sea turtles, manatees, dolphins, whales, etc.) shall be reported to the Wildlife Hotline immediately. Likewise, report any stranded, injured, trapped, entangled, or dead protected species to the Wildlife Hotline as soon as possible for further guidance on what action should be taken.
- Mariners shall check various communication media for general information regarding avoiding ship strikes and specific information regarding North Atlantic right whale sightings in the area.
  - Vessels 65 ft in length or longer must comply with the Right Whale Ship Strike Reduction Rule (50 CFR 224.105), which includes reducing speeds to 10 knots or less in Seasonal Management Areas.
    - Reduce speed to 10 knots or less when a right whale sighting is reported, mother/calf pairs, or groups of marine mammals are observed, when safety permits.
    - Secure all materials on vessels to prevent inadvertent loss overboard.

☐ All response vessels will follow marked channels and/or routes using the maximum water depth whenever possible.

☐ All response vessels shall operate at "Idle Speed/No Wake" at all times while in water depths where the draft of the vessel provides less than a 4-ft clearance from the bottom, and after a protected species has been observed in and has departed the area or adjacent to sensitive/environmentally important shorelines.

☐ Avoid vessel grounding, prop and bow/keel/skeg scarring, and prop washing in tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties.

☐ Avoid/minimize anchoring and spudding on tidal marsh, seagrass, and oyster reef habitats; anchor and spud on bare sand and mud bottoms, while avoiding archaeological sites or other historic properties. As soon as practically possible, consult with the State Historic Preservation Office (SHPO) and Tribal Historic Preservation Office (THPO) to determine proximity of archeological/historic sites and specific best management practices for those areas.

☐ Avoid/minimize shading of seagrasses with large vessels and barges for more than a few days; move large vessels and barges from over seagrasses onto bare sand or mud substrates when not undergoing active operations (such as in barge staging areas).

☐ Where equipment or crews must gain access across tidal marsh, seagrass, or oyster habitats, use shallow draft vessels to minimize disturbance, as applicable.

☐ Identify pinniped colonies in the response area as soon as possible and avoid disrupting the group as much as can be reasonably achieved. A response vessel should have a biologist experienced in marine mammal/protected species identification to observe and direct the response team to minimize impacts to groups of seals.

☐ If manatees are present, all water-based work and vessel operations must be in accordance with USFWS Standard Manatee Conditions for In-Water Activities (fws.gov). All response personnel shall be instructed about the presence of manatees and the need to avoid collisions with and injury to manatees. Advise all response personnel that there are civil and criminal penalties for harming, harassing, or killing manatees. Notify USFWS if manatees are observed.

On-water Mechanical Operations

(On-water Containment, Recovery, Protection)

☐ A biologist experienced in marine mammal/protected species identification or dedicated crew member is required for all skimming, booming, burning, and dispersant operations, with responsibility for avoiding marine mammals, sea turtles, birds, and reporting distressed or deceased animals.

☐ Stop operating mechanical equipment, including response vessels, immediately if a protected species is observed within a 50-ft radius and resume after the species has departed the area of its own volition.

☐ Entanglement:

- All in-water equipment (including hard and sorbent booms) must be properly secured with materials that reduce the risk of entanglement of marine species. Booms, lines, and other equipment must be made of materials that reduce the risk of entanglement of marine species. Keep all in-water lines (rope, chain and cable, including the lines to secure boom, buoys, anchors, etc.) stiff, taut, and non-looping. Floating line should be used as appropriate.
- Where feasible, the use of equipment with breakaway capabilities is advised to prevent or minimize the risk of entanglement of marine species.
- The Sea Turtle Stranding and Salvage Network (STSSN) should be contacted if sea turtles are entangled or entrapped during offshore operations.

☐ Entrapment:

- In-water equipment (including hard and sorbent boom) must be placed in a manner that does not entrap species within the work area or block access for them to navigate around the work area.
- If protected species become entrapped in an enclosed area, notify NMFS immediately. If observers note entrapped animals are visually disturbed, stressed, or their health is compromised, then activities may cease so the animal can either leave on its own or be moved under the direction of NMFS.
- The Sea Turtle Stranding and Salvage Network (STSSN) should be contacted if sea turtles are entangled or entrapped during offshore operations.

On-water Chemical Countermeasures

(Dispersants, Solidifiers, Herding Agents, Elasticity Modifiers)

☐ A biologist experienced in marine mammal/protected species identification or dedicated crew member is required for all skimming, booming, burning, and dispersant operations, with responsibility for avoiding marine mammals, sea turtles, birds, and reporting distressed or deceased animals.

☐ Where approved, dispersants should not be used within a 3-nautical mile radius of marine mammal species (e.g., whales, dolphins, seals, sealions, and manatees). The radius should increase to 10-nautical miles if North Atlantic right whales are observed in the area.

☐ Where approved, avoid dispersant applications near bird concentration areas and minimize bird exposure from wind drift of applied dispersant.

Other Countermeasures

(In-situ Burn, Bioremediation)

- ☐ A biologist experienced in marine mammal/protected species identification or dedicated crew member is required for all skimming, booming, burning, and dispersant operations, with responsibility for avoiding marine mammals, sea turtles, birds, and reporting distressed or deceased animals.
- ☐ Watch for and avoid marine mammals while operating vessels or aircraft involved directly or in support of in-situ burn operations. Marine species observers on the ignition vessel will monitor 3 areas prior to the burn (the area in front of the tow boats, oil concentrated in the boom, and any oil trailing behind the boom). A survey should be conducted in the burn area after the burn is complete and any distressed or dead marine mammals should be counted and reported to the Environmental Unit immediately.
- ☐ Avoid burning near bird concentration areas and minimize bird exposure from wind drift of smoke.
- ☐ Avoid burning near archaeological sites or other historic properties, particularly when these are not completely submerged.

Aircraft Operations

(Airplanes, Helicopters, Drones/Unmanned Aircraft Systems)

☐ Prior to operating Unmanned Aircraft Systems (UAS) coordinate with respective land managers to get specific UAS limitations.

☐ UAS flights should be limited to 100 feet above ground level (AGL) above resting birds on land or water (i.e., not in flight). Rotary aircraft should limit elevations to 300-400 feet AGL. If hazing/disturbances occur, increase altitude and report adjusted height to the Environmental Unit.

☐ Fixed-wing aircraft should follow NOAA marine mammal aerial survey protocols for speed (100 mph preferred), height (1000 feet AGL), and dwell time and for aircraft choice.

- For flyovers for identifying animals in the area are best done from aircraft that can fly low and slow and remain in an area for an extended period.

☐ Aircraft must stay >1,000 feet above bird nesting and aggregation sites and limit repetitive passes to minimize disturbance.

☐ Where deemed applicable, wildlife observers may be deployed on aircraft to report and record sightings of ESA species and/or other wildlife.

Vehicle Operations

(All-Terrain Vehicles, Automobiles/Trucks Heavy Equipment)

- ☐ Prior to vehicle operations, a biologist experienced in shorebird species identification is required to evaluate beaches for use by shorebirds (nesting, fledgling) each day.
- ☐ Prior to vehicle operations, the SHPO and THPO (if applicable) should be consulted to avoid disturbance of archaeological sites or other historic properties.
- ☐ Generally, preference is given to operations during daytime periods to minimize impacts to sea turtles and nesting shorebirds. Prior to any nighttime operations, it is highly recommended to consult with the Services for guidance.
- ☐ Utilize a lightweight vehicle with low tire pressure (10 psi), such as an All-Terrain Vehicle (ATV) or Mule whenever possible to reduce sand compaction and/or rutting.
- ☐ Utilize the same trackline for vehicle operations to minimize disturbance to multiple areas.
- ☐ Power wash vehicles prior to operating on beach areas to prevent spread of invasive species (e.g., Asian sand sedge).
- ☐ Enter the beach only at designated access points and proceed directly to the hard-packed sand near or below the high tide line. Stay below the tide line when driving if no oil is present and it is safe to do so.
- ☐ Do not drive in dune habitat.
- ☐ Avoid driving over the wrack line or areas of dense sargassum (otherwise known as seaweed), which may contain sea turtle hatchlings or newly hatched birds.
- ☐ Do not enter posted sea turtle or shorebird nest sites and minimize time spent around these sites. Most of these will be marked with posts and signs, but not all.
- ☐ Drive slowly. Travel should be slow enough to observe any bird eggs, chicks, or sea turtle hatchlings in the vehicle's line of travel. Be aware that bird chicks often feed along the water's edge. They may freeze in place rather than run away when ATVs or other vehicles approach.
- ☐ Check under and around vehicles and heavy equipment parked in shoreline areas before they are moved. Shorebirds (piping plover and red knot) are especially vulnerable when they are roosting at night, and extra care should be taken at these times. However, by this time of year, it is likely that these two federally threatened shorebird species have departed the area.

Shoreline Response Operations

(Protection/Containment: Pre-impact Debris Removal, Deflection/Protection Boom, Barriers/Berms, Flooding; Shoreline Treatment / Cleanup: Natural Recovery, Washing/Flushing, Physical Removal, Vegetation Cutting/Removal, Vacuum)

- ☐ In shallow nearshore areas with sensitive habitats, consider land-side access from roads, bulkheads, or other developed areas for operations.
- ☐ Avoid and minimize response disturbance to sensitive shoreline habitats and in particularly sand dunes and wetlands. Of particular concern are areas with Federally listed species in dune habitats such as tiger beetle, seabeach amaranth, and nesting birds. Contact the Environmental Unit to identify updated locations with these listed species in dune habitats.
- ☐ Where equipment or crews must access areas across tidal marsh, seagrass, or oyster habitats, use shallow draft vessels or specialized equipment with low pressure/flotation tires, equipment mats, walk boards, or other comparable methods to minimize disturbance, as applicable.
- ☐ Keeping clean wrack in general proximity is ideal, but it is not necessary to move it a substantial distance and back—use reasonable judgment.
- ☐ Following response work on beaches, return the beach to its original profile at the end of each day.
- ☐ Do not enter sites where birds are nesting or roosting and maintain a buffer of at least 300 ft from these sites. If birds are flushed, move away from the area, and observe a larger buffer distance to avoid and minimize disturbance.
- ☐ When working in or near bird migratory/wintering areas, work crews should be limited to the minimum number of personnel and equipment required to complete response activities in an efficient time frame and as is feasible to minimize disturbance.
- ☐ Be aware of the potential for sea turtle nesting activity if any operations are planned on Atlantic Ocean-facing sand beaches. Nests, eggs, and hatchlings may be present from May through November.
- ☐ Adult sea turtles, crawls, nests, eggs, hatchlings, and critical habitat should be protected during response activities on sea turtle nesting beaches, including hatchling turtles as they emerge from the nest and crawl to the sea. If a sea turtle nest is inadvertently excavated during assessment or response activities, all work shall cease in that area immediately and the Environmental Unit should be contacted.
- ☐ Upon locating any dead, injured, or sick sea turtle, birds, or marine mammals, or if eggs or nests are disturbed during response activity, initial notification must be made to the Environmental Unit as soon as possible. The Environmental Unit will make further notifications to the appropriate agency contacts.
- ☐ Contact the Unified/Incident Command (UC/IC) and Environmental Unit prior to conducting any response efforts that require substantial ground disturbance as additional SHPO coordination may be required. Federally recognized tribes with interest in the area and the THPO may be contacted if applicable.
- ☐ Cease all activities involving subsurface disturbance and immediately contact the UC/IC and Environmental Unit if prehistoric/historic artifacts, such as pottery or ceramics, projectile points, dugout canoes, metal implements, historic building materials, or any other physical remains that could be associated with Native American, early European, or American settlement are encountered at any time (and leave all artifacts in place). The SHPO and/or THPO must be notified. Response activities

shall not resume without verbal and/or written authorization from the UC/IC in consultation with the designated Historic Preservation Specialist (HPS) and document decisions; if there is no designated HPS then the UC/IC should receive guidance from the SHPO and/or THPO. If unmarked human remains are encountered during response activities, stop all work immediately and report to the UC/IC and Environmental Unit through your chain of command.

Staging Areas / Support Facilities

☐ Equipment and material staging areas must be located outside of areas of natural/native vegetation and known endangered species habitats, including federally threatened plant(s) that may be present in dunes. Areas proposed for equipment and material staging should be determined in consultation with the SHPO and/or THPO to avoid disturbance of archaeological sites or other historic properties. Contact the Environmental Unit (if established) for assistance.

☐ Use existing beach access areas and trails only.

☐ All trash resulting from the response should be removed from the area as appropriate or disposed of properly in covered wildlife-proof trash receptacles.

Waste Management

☐ All trash resulting from the response should be removed from the area as appropriate or disposed of properly in covered wildlife-proof trash receptacles.

Grounded or Displaced Vessel Response/Removal Operations

- ☐ Avoid and minimize response disturbance to sensitive benthic and shoreline habitats including tidal marshes, oyster reefs, seagrasses, sand beaches, and dunes.
- ☐ Contact the Environmental Unit prior to conducting any response efforts that require significant ground disturbance as U.S. Army Corps of Engineers (USACE) and/or State permits may be required. Additionally, substantial ground disturbance beyond the initial disturbance caused by the grounding may require additional SHPO coordination for historic sites and/or THPO for tribal coordination.
- ☐ Contact the Environmental Unit if significant sediment disturbance is anticipated, as further coordination with USACE may be required.
- ☐ Contact the Environmental Unit if filling of wetlands or surface waters or dredging that creates or expands surface waters is anticipated, as emergency permitting from State Agencies may be required.
- ☐ Turbidity control measures may be implemented if significant turbidity increases are expected during response actions. Such control measures include:
    - Install floating turbidity barriers with weighted skirts that extend to within 1-ft of the bottom around all work areas that are in, or adjacent to, surface waters, if heavy turbidity is expected.
    - Use these turbidity barriers throughout vessel removal to control erosion and siltation and ensure that turbidity levels within the project area do not exceed background conditions (i.e., the normal water quality levels from natural turbidity).
    - Position turbidity barriers in a way that does not block species entry to or exit from designated critical habitat.
    - Monitor and maintain turbidity barriers in place until the authorized work has been completed and the water quality in the project area has returned to background conditions.
- ☐ Avoid response vessel grounding, prop and bow/keel/skeg scarring, and prop washing in tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties.
- ☐ Avoid/minimize anchoring and spudding on tidal marsh, seagrass, and oyster reef habitats; anchor and spud on bare sand and mud bottoms, while avoiding archaeological sites or other historic properties. Consult with the SHPO and/or THPO to determine proximity of archeological/historic sites.
- ☐ If spudding on seagrasses cannot be avoided, fill spud holes to grade with clean sand, as feasible, to minimize impacts. Consult the Environmental Unit for any remediation requirements.
- ☐ Avoid/minimize shading of seagrasses with large vessels and barges for more than a few days; move large vessels and barges from over seagrasses onto bare sand or mud substrates when not undergoing active operations (such as in barge staging areas).
- ☐ Prior to hoisting, refloating, or repositioning grounded or displaced vessels, work crews should evaluate the immediate area and determine an ingress/egress path that will have the least impact to tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties. Contact the Environmental Unit for assistance.
- ☐ Temporary stakes/buoys should be used to mark the ingress/egress path, if applicable, to assist in staying on course and to avoid the areas of greatest tidal marsh, oyster reef, and seagrass habitat extent and quality.

- ☐ In shallow areas with sensitive shoreline and bottom habitats, consider land-side access from roads, bulkheads, or other developed or disturbed areas for response operations, where feasible.
- ☐ Where equipment or crews must access grounded or displaced vessels across tidal marsh, seagrass, or oyster habitats, use shallow draft vessels or specialized equipment with low pressure/flotation tires, equipment mats, walk boards, or other comparable methods to minimize disturbance, as applicable.
- ☐ Avoid pulling grounded or displaced vessels or other items across or onto tidal marsh, seagrass, and oyster reef habitats - items should be hoisted or refloated if possible. Use of lift bags, rollers, equipment mats, and other methods should be evaluated to minimize impacts, such as rutting and keel scarring.
- ☐ Avoid digging, jetting, excavation, and similar methods in tidal marsh, seagrass, oyster reef habitats, and archaeological sites or other historic properties to refloat or reposition displaced vessels.
- ☐ If the above suite of habitat based BMPs cannot be applied, further USACE and State permits (see above) and Essential Fish Habitat (EFH) consultation may be required.

For further guidance and assistance with Best Management Practices (BMPs) during a response/incident, please contact the Environmental Unit (if established). BMPs that are utilized should be documented by the FOSC via the RRT3 ESA/EFH Biological Evaluation Guidance & Form for USCG Fifth District Coastal Zone.

ENVIRONMENTAL POINTS OF CONTACT

Primary Environmental Agencies / Organizations

If the Environmental Unit is not stood up, the key points of contact for environmental, wildlife, and historic preservation concerns during an oil spill response are provided below.

U.S. Coast Guard Fifth District Response Advisory Team (DRAT)

- David Pugh, david.e.pugh1@uscg.mil, 757-373-4133 (cell)
- Elisha Cook, elisha.fs.cook@uscg.mil, 757-630-1430 (cell)

National Oceanic and Atmospheric Administration (NOAA) Scientific Support Coordinator (SSC)

- Frank Csulak, frank.csulak@noaa.gov, 732-371-1005

U.S. Fish and Wildlife Service (USFWS) Response Coordinators

- Sarah Shaeffer (NJ, NY, DE, Eastern PA/Delaware Watershed), sarah_scheaffer@fws.gov, 609-833-1476
- Jo Ann Banda (MD, Western PA, VA, WV, DC), joann_banda@fws.gov, 804-824-2413 (office), 804-694-7647 (cell)

February 2022.2

RECORD OF CHANGES

Maintenance of this plan is the responsibility of the Regional Response Team III (RRT3) Consultation, Natural Resources, and Damage Assessment (CNRDA) Workgroup. Minor changes may be made periodically, and an update and review will be conducted at least once per year, at a minimum, to validate points of contact. The most current version of the plan will be posted on the RRT3 Website under the Regional Contingency Plan (RCP) Appendix 9 and the USCG District 5 District Response Advisory Team (D5 DRAT) Sharepoint site.

FEBRUARY 2022 EDITION

Change Number	Date of Change/Review	Person & Agency Making Change	Description of Change/Update

Endangered Species Act and Essential Fish Habitat Consultation Guidance for Coastal Zone

The U.S. Coast Guard (USCG) Fifth District units will use this biological evaluation (BE) form to conduct Endangered Species Act (ESA) Section 7 and Essential Fish Habitat (EFH) consultation with the Department of Commerce National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS), and U.S. Department of the Interior's (DOI) U.S. Fish and Wildlife Service (USFWS). These agencies are referred to as "the Services." This form will be used to cover oil spill and/or hazardous substance response actions within the Fifth Coast Guard District coastal zone, which includes Delaware, District of Colombia, Maryland, portions of New Jersey, North Carolina, portions of Pennsylvania, and Virginia.

Background and Purpose

The purpose of this document is to help the Federal On-Scene Coordinator (FOSC) determine whether to initiate ESA consultation and EFH coordination in accordance with 50 CFR § 402.05 and 50 CFR § 600.920(a)(1) and to assist the FOSCs through the process.

The FOSC should check the following databases and contacts for each of the Services to help identify the presence of federally listed threatened or endangered species or designated Critical Habitats or EFH:

- Environmental Response Management Application (ERMA): https://erma.noaa.gov/atlantic#/
  - Geographic Response Strategies (GRS): Located in ERMA under 'Response Planning – Area Contingency Plans – Sector [Delaware Bay, Maryland NCR, Hampton Roads, North Carolina]'
  - NOAA Environmental Sensitivity Index (ESI) Maps: Located in ERMA under 'Natural Resources, Habitats, & Managed Areas – Environmental Sensitivity Index'
- NOAA ESA Species Matrix: Posted on RRT III website at https://www.nrt.org/site/doc_list.aspx?site_id=72
- Greater Atlantic Region ESA Section 7 Mapper: https://www.fisheries.noaa.gov/new-england-mid-atlantic/consultations/section-7-species-critical-habitat-information-maps-greater
- EFH Mapper: https://www.habitat.noaa.gov/apps/efhmapper/
- Atlantic Marine Assessment Program for Protected Species (AMAPPS) Marine Mammal Model Viewer: https://apps-nefsc.fisheries.noaa.gov/AMAPPSviewer/
- Information for Planning and Consultation (IPaC) within the USFWS Environmental Conservation Online System (ECOS): https://ecos.fws.gov/ipac/

The FOSC should then evaluate response actions and their potential impacts, if any, on federally listed threatened or endangered species or designated Critical Habitats or EFH. The scope of the consultation is focused on the agency's response actions during an incident, **NOT** the incident itself.

The three ESA thresholds, which are used to determine action necessary by the FOSC, are:

(1) **No Effect** (none at all, negative or positive);

(2) **May Affect**; Not Likely to Adversely Affect, (NLAA); and

(3) **May Affect; Likely to Adversely Affect** (LAA).

The two EFH thresholds, which are used to determine action necessary by the FOSC, are:

(1) **Would Not Adversely Affect** (WNAA); and

(2) **May Adversely Affect** (MAA).

Whenever an FOSC makes a determination that federal response actions **may affect** ESA-listed (threatened or endangered) species and/or designated Critical Habitat or **may adversely affect** EFH, **the action agency shall initiate consultation protocols**. For emergency consultation, the FOSC shall initiate this consultation, as soon as practicable, via verbal or email notification. The form shall be sent via email to the Services after the consultation is initiated.

Responders should not delay emergency response actions while awaiting a response from the Services. If the FOSC determines consultations are not practicable during emergency response operations, refer to the NRT's Post-Response Procedures guidance for ESA Section 7 and EFH compliance requirements.

Depending on the scale and scope of emergency response actions, pre-spill planning consultations can minimize the level of effort of emergency consultation(s) and, in certain circumstances, even alleviate the need for emergency consultation(s). If pre-spill planning consultations were completed with the Services, BMPs may be incorporated into the GRSs, Area Contingency Plans (ACP), and Regional Contingency Plans (RCP).

More guidance regarding Section 7 consultation can be found in the 2001 Inter-agency Memorandum of Agreement Regarding Oil Spill Planning and Response Activities under the Federal Water Pollution Control Act's National Oil and Hazardous Substances Pollution Contingency Plan (2001 MOA) and the NRT's National Environmental Compliance (NEC) Subcommittee ESA guidance page at NRT.org[1]. The 2001 MOA provides a framework for cooperation and participation among parties involved in oil spill planning and response. It outlines procedures to streamline ESA compliance process before, during, and after an incident. EFH consultations should be completed simultaneously with ESA Section 7 consultations. Additional NMFS ESA Section 7 consultation guidance can be found on the Greater Atlantic Region[2] site and for USFWS guidance can be found on the Northeast Region[3] site.

For all Section 7 Consultations

The regional NOAA SSC and/or DOI Regional Environmental Officer **shall** be informed whenever the FOSC engages in emergency consultation with the Services.

The NOAA SSC may be able to facilitate communications between the USCG and the Services; however, it is the sole responsibility of the FOSC to initiate, conduct, and complete the consultation.

The DOI Regional Environmental Officer may also be able to facilitate communications between the action agencies and USFWS.

U. S. Coast Guard (USCG) District Incident Management and Preparedness Advisors (IMPAs) and District Response Advisory Teams (DRATs) are excellent resources for all required consultations (ESA, EFH, State Historic Preservation Office (SHPO), and Tribal Historic Preservation Office (THPO)).

The USCG IMPA and DRAT are available 24/7 via District command centers.

ESA/EFH Consultation Form

Section 7 primary points of contact for RRT3 coastal zone area of responsibility and North Carolina (under USCG District 5) are included in Enclosure (1). The Section 7 Consultation Form is included as Enclosure (2).

When used for emergency consultation this form is intended to provide as much detailed information as possible to the Services within 48 hours of the federal action agency undertaking emergency response actions. It is not intended to be comprehensive, and **responders should not delay emergency response actions while awaiting a response from the Services**. This form assists FOSCs in meeting their statutory obligations to conduct emergency consultation under Section 7 of the ESA and/or designated EFHs. This form is also designed to document communication efforts between the Action Agencies and the Services as well as provide a consistent template for use in compiling relevant information and recommendations during emergency response operations.

Note: The Services will review the supplied information and respond with Best Management Practices (BMP) to mitigate potential impacts to any ESA-listed (threatened or endangered) species and/or designated Critical Habitat and/or EFH. The measures and BMPs are then incorporated into response actions and specialists may be brought into the response to provide additional oversight and guidance via Pollution Removal Funding Authorization (PRFA).

Once this form is submitted, the Services will consider the proposed response actions and use ENCLOSURE 2: DOCUMENTATION OF ESA SECTION 7 AND EFH EMERGENCY CONSULTATION DURING EMERGENCY RESPONSE ACTIVITIES – USFWS/NMFS RESPONSE to provide recommendations, which may include information on species and designated Critical Habitats in the area, suggested conservation measures / best management practices, etc.

ENCLOSURE 2: ESA SECTION 7 / EFH CONSULTATION FORM

This form will be utilized by the U.S. Coast Guard (USCG) Federal On-Scene Coordinator (FOSC) for pre-spill, emergency, and post-response Endangered Species Act (ESA) Section 7 consultations. It will be filled out by the USCG and used by the Department of the Interior's (DOI) U.S. Fish & Wildlife Service (USFWS) and the National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS) to review response actions for potential impacts to federally listed species. The form provides information to initiate and conclude emergency consultations under ESA §7 and to document (1) a "No Effect" determination, (2) to request technical assistance, or (3) to document up to the May Affect, Not Likely to Adversely Affect threshold. Additionally, information beyond this form may be required by the Services.

FOSCs (or their designated representative) should complete Section I after initial notification is made to the Services. Section I should be filled out with the best available information accounting for all response actions taken or being considered. For emergency consultations, only tables A – E must be completed prior to forwarding to the Services. FOSCs may work with Service representatives during the emergency consultation process to determine the presence and effects to species/habitats and implementation of conservation measures in Tables F - L. **Section II is intended to be submitted blank to the Services, so the Services can both acknowledge the request for consultation as well as begin to consider the FOSC's actions or proposed actions during the emergency response.** This form should also be used to provide updates to the Services as the incident evolves and FOSC actions are adjusted based on operational objectives. When needed and applicable, this form will also be completed to inform and evaluate additional needs for compliance with the following authorities: Magnuson-Stevens Fishery Conservation and Management Act (for Essential Fish Habitat [EFH]), Migratory Bird Treaty Act (MBTA), Marine Mammal Protection Act (MMPA), Coastal Barrier Resources Act (CBRA), Bald and Golden Eagle Protection Act (BGEPA).

A. CONSULTATION DETAILS	
Name of Unit Requesting Consultation	Click or tap here to enter text.
Type of Consultation Requested	Select consultation type from dropdown menu.
FOSC	Rank/Name Email Phone Number
FOSCR	Rank/Name Email Phone Number
Person Completing Form	Rank/Name Email Phone Number
Date Form Initially Completed	Date
Date Consultation / Technical Assistance Completed	Date
Are there **previously completed ESA consultation documents** that are applicable to this area / action (e.g., dispersants, in-situ burning, surface washing agents)	☐ Yes ☐ No List any previous consultations documents.

B. INCIDENT / EVENT DETAILS	
Name of Incident	Incident Name
Date of Incident	Enter Date
Type of Incident / Event (e.g., vessel grounding, vessel collision, pipeline, transfer, training/exercise)	Click or tap here to enter text.
Product(s) Released / Discharged	Click or tap here to enter text.
Volume Released / Discharged (in gallons)	Enter volume in gallons.
Potential Volume (in gallons)	Enter volume in gallons.
Has the release / discharge been stopped, ongoing, or is status unknown?	Click or tap here to enter text.
Is the released / discharge contained, spreading, or is the status unknown?	Click or tap here to enter text.
Latitude/Longitude for action area (Decimal degrees and datum [e.g., 27.71622°N, 80.25174°W NAD83; online conversion: https://www.fcc.gov/media/radio/dms-decimal])	Latitude°N Longitude°W Choose Datum
Location (nearest landmark / town)	Click or tap here to enter text.
Location Type (check all that apply below) ☐ Port / Industrial / Canal ☐ Riverine ☐ Inshore / Estuarine ☐ Nearshore / Coastal ☐ Offshore / EEZ ☐ Lake / Lacustrine (freshwater) ☐ Wetland (freshwater)	Click or tap here to enter text.
Please attach any maps, aerial photographs, or additional information that will support the information in this consultation form. Examples of such supporting documentation include, but are not limited to: • Aerial images of response action area and surrounding area.	

B. INCIDENT / EVENT DETAILS

- Map of response action area with elements proposed (polygons showing proposed response action elements).
- Map of response action area with critical habitat units or sensitive habitats overlay (e.g., seagrass beds, Essential Fish Habitat, etc.).

C. INCIDENT AND RESPONSE ACTIONS

Describe the incident/event and proposed response action objectives.
Describe in detail the equipment and methods needed; the anticipated schedule (e.g., days, weeks, months) for each phase of the response; long-term vs. short-term impacts; duration of short-term impacts; dust, erosion, and sedimentation controls; restoration areas; whether the response actions are part of a larger action or plan; and what approvals will need to be obtained. Attach the ICS-201 and other ICS forms as applicable.

☐ All-Terrain Vehicles (ATVs)	Click or tap here to enter text.
☐ Boats / Airboats	Click or tap here to enter text.
☐ Drones / Unmanned Aerial Systems (UASs)	Click or tap here to enter text.
☐ Heavy Equipment	Click or tap here to enter text.
☐ Helicopters	Click or tap here to enter text.
☐ Staging Areas	Click or tap here to enter text.
☐ Truck or other automobile	Click or tap here to enter text.
☐ OTHER (description in notes)	Click or tap here to enter text.

E. RESPONSE ACTION AREA / HABITAT TYPES

Provide a description of the existing environment (e.g., vegetation type, substrate type, tidal/riverine/estuarine, hydrology and drainage patterns, current flow and direction) and land uses (e.g., public, residential, commercial, industrial, agricultural). Describe all areas that may be directly or indirectly affected by the response action(s). If possible, provide name of waterbody in the "Details / Notes" column.

The information provided in this section will be used in both ESA Emergency Consultation and Essential Fish Habitat (EFH) analyses, so please provide additional information to the maximum extent practicable, particularly if there is an EFH Habitat Areas of Particular Concern (HAPC) that may be found in the response action area. The Essential Fish Habitat Mapper tool may be used to identify EFH and/or HAPCs in the action area: https://www.habitat.noaa.gov/apps/efhmapper/efhreport/

Click or tap here to enter text.

Habitat Type (check all that occur in the response action area)	**Habitat Exposed / Not Exposed to response action(s)?**	**Details / Notes** (Provide details on response actions occurring in identified habitats)
☐ Artificial Reefs (including oyster reefs)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Beach	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Coastal Lagoon	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Corals	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Dune	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Emergent Marsh	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.

E. RESPONSE ACTION AREA / HABITAT TYPES		
☐ Freshwater ☐ Intermediate ☐ Brackish ☐ Saltwater		
☐ Forested Wetland (swamp)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Intertidal Sand / Mud / Algal Flats	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Lake / Lacustrine (freshwater)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Marine (open water)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Marsh (tidal / salt)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Riverine / Riparian (freshwater)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Rocky Intertidal	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Submerged Aquatic Vegetation	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ Wetland (freshwater)	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ OTHER (list below) Enter habitat type.	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.
☐ OTHER (list below) Enter habitat type.	☐ Exposed ☐ Not Exposed	Click or tap here to enter text.

F. NMFS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED

(Optional to complete prior to Emergency Consultation)

Identify all species and critical habitat under NMFS jurisdiction that may be found in the response action area.

- For Sector Delaware Bay, Maryland-NCR, or Virginia refer to the Greater Atlantic Region ESA Section 7 Mapper to identify ESA-listed species and critical habitat in the action area: https://www.fisheries.noaa.gov/new-england-mid-atlantic/consultations/section-7-species-critical-habitat-information-maps-greater
- For Sector North Carolina refer to the South Atlantic Species and Critical Habitat List: https://www.fisheries.noaa.gov/southeast/consultations/north-carolina

If all consequences of proposed response actions occur in a location that does not contain any listed or proposed NMFS species or designated/proposed critical habitats, OR if those response actions and their effects have been covered under previous existing consultations, please check the appropriate box below. If one of these boxes is checked, you may skip this section.

F. NMFS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

☐ All direct and indirect effects of the proposed response actions occur in a location that does not contain any listed or proposed NMFS species or designated/proposed critical habitats.

☐ All direct and indirect effects of the proposed response actions have been accounted for under an existing ESA Section 7 consultation.

Threatened / Endangered Species	Critical Habitat	Determinations (see definitions below)	For "No Effect" select justification
☐ List species.	☐	Select a determination.	Select most appropriate.

☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.

Determination Definitions (applicable to both species and designated critical habitat determinations):

NE = no effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed or proposed species or designated/proposed critical habitat.

NLAA = may affect, not likely to adversely affect. This determination is appropriate when the proposed action is not likely to adversely impact any listed or proposed species or designated/proposed critical habitat, or there may be beneficial effects to these resources. The USCG would request the Services to concur with the not likely to adversely affect determination. This conclusion is appropriate when effects to the species or critical habitat will be wholly beneficial, discountable, or insignificant. Beneficial effects are contemporaneous positive effects without any adverse effects to the species or habitat. Insignificant effects relate to the size of the impact, while discountable effects are those that are extremely unlikely to occur. Based on best judgment, a person would not: (1) be able to meaningfully measure, detect, or evaluate insignificant effects; or (2) expect discountable effects to occur. If the Services concur in writing with the Action Agency's determination of "is not likely to adversely affect" listed species or critical habitat, the §7 consultation process is completed.

LAA = may affect, likely to adversely affect. This determination is appropriate when the proposed action is likely to adversely impact any listed or proposed species or designated/proposed critical habitat. The USCG would request formal

F. NMFS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

consultation with the Services for a response action(s) with a likely to adversely affect determination; the Services' response would be a biological opinion as the concluding document. This conclusion is reached if any adverse effect to listed species or critical habitat may occur as a direct or indirect result of the proposed action or its cumulative effects, and the effect is not discountable or insignificant. In the event the overall effect of the proposed action is beneficial to the listed species or critical habitat but may also cause some adverse effect on individuals of the listed species or segments of the critical habitat, then the determination is "likely to adversely affect." Any LAA determination requires formal §7 consultation and will require additional information.

G. USFWS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

Identify all species and critical habitat under USFWS jurisdiction that may be found in the response action area.

- The USFWS Information for Planning and Consultation (IPaC) tool may be used to identify ESA-listed species and critical habitat in the action area: https://ecos.fws.gov/ipac/

If all consequences of proposed response actions occur in a location that does not contain any listed or proposed USFWS species or designated/proposed critical habitats, OR if those response actions and their effects have been covered under previous existing consultations, please check the appropriate box below. If one of these boxes is checked, you may skip this section.

☐ All direct and indirect effects of the proposed response actions occur in a location that does not contain any listed or proposed USFWS species or designated/proposed critical habitats.

☐ All direct and indirect effects of the proposed response actions have been accounted for under an existing ESA Section 7 consultation.

G. USFWS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.

Determination Definitions (applicable to both species and designated critical habitat determinations):

NE = no effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed or proposed species or designated/proposed critical habitat.

NLAA = may affect, not likely to adversely affect. This determination is appropriate when the proposed action is not likely to adversely impact any listed or proposed species or designated/proposed critical habitat, or there may be beneficial effects to these resources. The USCG would request the Services to concur with the not likely to adversely affect determination. This conclusion is appropriate when effects to the species or critical habitat will be wholly beneficial, discountable, or insignificant. Beneficial effects are contemporaneous positive effects without any adverse effects to the species or habitat. Insignificant effects relate to the size of the impact, while discountable effects are those that are extremely unlikely to occur. Based on best judgment, a person would not: (1) be able to meaningfully measure, detect, or evaluate insignificant effects; or (2) expect discountable effects to occur. If the Services concur in writing with the Action Agency's determination of "is not likely to adversely affect" listed species or critical habitat, the §7 consultation process is completed.

LAA = may affect, likely to adversely affect. This determination is appropriate when the proposed action is likely to adversely impact any listed or proposed species or designated/proposed critical habitat. The USCG would request formal consultation with the Services for a response action(s) with a likely to adversely affect determination; the Services' response would be a biological opinion as the concluding document. This conclusion is reached if any adverse effect to listed species or critical habitat may occur as a direct or indirect result of the proposed action or its cumulative effects, and the effect is not discountable or insignificant. In the event the overall effect of the proposed action is beneficial to the listed species or critical habitat but may also cause some adverse effect on individuals of the listed species or segments of the critical habitat, then the determination is "likely to adversely affect." Any LAA determination requires formal §7 consultation and will require additional information.

H. ESSENTIAL FISH HABITAT AREAS OF PARTICULAR CONCERN EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

Identify all EFH species and Habitat Areas of Particular Concern (HAPC) that may be found in the response action area.

- The Essential Fish Habitat Mapper tool may be used to identify EFH and/or HAPCs in the action area: https://www.habitat.noaa.gov/apps/efhmapper/efhreport/

If all consequences of proposed response actions occur in a location that does not contain any EFH species or HAPCs, OR if those response actions and their effects have been covered under previous existing consultations, please check the appropriate box below. If one of these boxes is checked, you may skip this section.

☐ All direct and indirect effects of the proposed response actions occur in a location that does not contain any EFH species or HAPCs.

H. ESSENTIAL FISH HABITAT AREAS OF PARTICULAR CONCERN EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

☐ All direct and indirect effects of the proposed response actions have been accounted for under an existing EFH consultation.

EFH Species	HAPCs	Determinations (see definitions below)	For "Would not adversely affect" select justification

☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.

Determination Definitions (applicable to both EFH and HAPC determinations):
WNAA = would not adversely affect. Would not adversely affect is the appropriate determination if the response action and the stressors of that action would not affect EFH.
MAA = may adversely affect. Adverse Effects are anything that changes the quality or quantity of EFH.

I. EFFECTS OF RESPONSE ACTIONS & MEASURES TO REDUCE IMPACTS TO LISTED SPECIES AND CRITICAL HABITATS
(Optional to complete prior to Emergency Consultation)

Explain the potential beneficial and adverse effects to each species and/or critical habitats identified in the above tables.

Describe what, when, and how the species and/or critical habitat will be impacted and the likely response to the impact. Be sure to include direct, indirect, and cumulative impacts, and where possible, quantify those effects. If species are present (or potentially present) and will not be adversely affected, describe your rationale. If species are unlikely to be present in the general area or action area, explain why. Describe your

I. EFFECTS OF RESPONSE ACTIONS & MEASURES TO REDUCE IMPACTS TO LISTED SPECIES AND CRITICAL HABITATS
(Optional to complete prior to Emergency Consultation)

rationale if designated or proposed critical habitats are present and will not be adversely affected. This justification provides documentation for your administrative record, avoids the need for additional correspondence, and helps expedite review.

NOTE: Species selected as "No Effect" with justification in the above tables do not need to be addressed.

Click or tap here to enter text.

Explain the measures taken to reduce adverse effects to the species identified above.

For each species for which impacts were identified, describe any conservation measures (e.g., best management practices [BMPs]) that will be implemented to avoid or minimize the impacts. Conservation measures are designed to avoid or minimize effects to listed species and critical habitats or further the recovery of the species under review. Conservation measures are considered part of the proposed actions and their implementation is required. Any changes to, modifications of, or failure to implement these conservation measures may result in a need to reinitiate this consultation.

Click or tap here to enter text.

Frequently Recommended BMPs

This checklist provides standard BMPs recommended by NMFS and USFWS or developed in coordination with the Services. Please select any BMPs that will be implemented (website links to BMPs are provided below).

☐ Environmental BMPs for Oil Spill Response in Regional Response Team 3 Coastal Zone	[placeholder for link to document on RRT III website]
☐ NMFS EFH BMPs for Certain Response Activities to Accidental Discharges of Oil and Other Hazardous Materials in the Southeastern United States	https://media.fisheries.noaa.gov/dam-migration/sero_hazmat_bmps.pdf
☐ NMFS Marine Life Viewing Guidelines and Distances	https://www.fisheries.noaa.gov/topic/marine-life-viewing-guidelines#guidelines-&-distances
☐ NMFS Measures for Reducing the Entrapment Risk to Protected Species	https://media.fisheries.noaa.gov/dam-migration/entrapment_bmps_final.pdf
☐ NMFS Sea Turtle Handling and Resuscitation Requirements	https://media.fisheries.noaa.gov/dam-migration/sea_turtle_handling_and_resuscitation_measures.pdf
☐ NMFS Sturgeon Resuscitation Guidelines	https://media.fisheries.noaa.gov/dam-migration/sturgeon_resuscitation_card_06122020_508.pdf
☐ NMFS Vessel Strike Avoidance Measures and Reporting for Mariners	https://media.fisheries.noaa.gov/dam-migration/vessel_strike_avoidance_february_2008.pdf
☐ USFWS Avoidance and Minimization Measures for Piping Plover and Red Knot for Shoreline Activities	https://www.fws.gov/southeast/pdf/best-management-practice/piping-plover-and-red-knots-for-shoreline-activities-in-louisiana.pdf

I. EFFECTS OF RESPONSE ACTIONS & MEASURES TO REDUCE IMPACTS TO LISTED SPECIES AND CRITICAL HABITATS (Optional to complete prior to Emergency Consultation)	
☐ USFWS Standard Manatee In-Water Conditions	https://www.fws.gov/southeast/pdf/guidelines/standard-manatee-conditions.pdf
☐ National Response Team General BMPs or Conservation Measures (Appendix D)	https://www.nrt.org/sites/2/files/Pre-Spill_BEOutline_%20updated%2031Oct2018%20FINAL.docx
☐ Caribbean Regional Response Team BMPs for Oil Spill Response Operations	https://nrt.org/sites/33/files/App%207%20CRRT%20Compilation%20of%20BMPs%20Revised% 204_2020.pdf
☐ OTHER (list below) Name of BMP.	Provide a link to BMP.

J. MARINE MAMMALS
(Optional to complete prior to Emergency Consultation)

The Marine Mammal Protection Act (MMPA) prohibits the taking (including disruption of behavior, entrapment, injury, or death) of all marine mammals. The MMPA allows limited exceptions to the take prohibition, if authorized, such as the incidental take of marine mammals. The Atlantic Marine Assessment Program for Protected Species (AMAPPS) Marine Mammal Model Viewer (https://apps-nefsc.fisheries.noaa.gov/AMAPPSviewer/) maps marine life sightings and ocean conditions to help inform marine resource management decisions. The maps use whale, dolphin, and porpoise sightings data and can be sued to predict marine mammal densities.

Marine Mammals that *may be* present within the response action area	**Details / Notes** (If applicable, indicate and describe the species that may be present in the response action area)
Dolphins ☐ Yes ☐ No	Click or tap here to enter text.
Manatees ☐ Yes ☐ No	Click or tap here to enter text.
Porpoise ☐ Yes ☐ No	Click or tap here to enter text.
Seals ☐ Yes ☐ No	Click or tap here to enter text.
Whales ☐ Yes ☐ No	Click or tap here to enter text.

The following questions are designed to allow the NMFS and/or USFWS to quickly determine if response actions have the potential to result in take to marine mammals. If the information provided indicates that incidental take is possible, further discussion with the NMFS and/or USFWS is required.

(a) Is your action occurring in or on marine or estuarine waters? ☐ Yes ☐ No

(b) If yes, is your action likely to cause large-scale, ecosystem level impacts to the quality (e.g., salinity, temperature) of marine or estuarine waters? ☐ Yes ☐ No

(c) If yes, describe actions further using checkboxes in the table below. Does your action involve any of the following:

J. MARINE MAMMALS
(Optional to complete prior to Emergency Consultation)

☐ Yes ☐ No	Use of active acoustic equipment (e.g., echosounder) producing sound below 200 kHz
☐ Yes ☐ No	In-water construction or demolition
☐ Yes ☐ No	Temporary or fixed use of active or passive sampling gear (e.g., nets, lines, traps; turtle relocation trawls)
☐ Yes ☐ No	In-water explosive detonation
☐ Yes ☐ No	Aquaculture
☐ Yes ☐ No	Restoration of barrier islands, levee construction, or similar projects
☐ Yes ☐ No	Fresh-water river diversions
☐ Yes ☐ No	Building or enhancing areas for water-related recreational use or fishing opportunities (e.g., fishing piers, bridges, boat ramps, marinas)
☐ Yes ☐ No	Dredging or in-water construction actions to change hydrologic conditions or connectivity, create breakwaters and living shorelines, etc.
☐ Yes ☐ No	Conducting driving of sheet piles or pilings
☐ Yes ☐ No	Use of floating pipeline during dredging actions

If you checked "Yes" to any of the actions immediately above, or if the action *could impact* the quality of marine or estuarine waters, please describe the nature of the actions in more detail or indicate which section of the form already includes these descriptions.

Click or tap here to enter text.

If not already identified in Table I, please describe any additional BMPs or conservation measure that may be implemented for marine mammals.

☐ OTHER (list below) Name of BMP.	Provide a link to BMP.
☐ OTHER (list below) Name of BMP.	Provide a link to BMP.

K. BALD EAGLES
(Optional to complete prior to Emergency Consultation)

Are bald eagles present in the response area? ☐ Yes ☐ No

If YES, the following conservation measures should be implemented per the National Bald Eagle Management Guidelines: https://www.fws.gov/northeast/ecologicalservices/eagle.html

- If bald eagle breeding or nesting behaviors are observed or a nest is discovered or known, all actions (e.g., walking, camping, clean-up, use of a UTV, ATV, or boat) should avoid the nest by a minimum of 660 feet. If the nest is protected by a vegetated buffer where there is no line of sight to the nest, then the minimum avoidance distance is 330 feet. This avoidance distance shall be maintained from the onset of breeding/courtship behaviors until any eggs have hatched and eaglets have fledged (approximately 6 months).
- If a similar action (e.g., driving on a roadway) is closer than 660 feet to a nest, then you may maintain a distance buffer as close to the nest as the existing tolerated action.

K. BALD EAGLES
(Optional to complete prior to Emergency Consultation)

- If a vegetated buffer is present and there is no line of sight to the nest and a similar action is closer than 330 feet to a nest, then you may maintain a distance buffer as close to the nest as the existing tolerated action.
- In some instances, actions conducted at a distance greater than 660 feet of a nest may result in disturbance. If an action appears to cause initial disturbance, the action shall stop and all individuals and equipment will be moved away until the eagles are no longer displaying disturbance behaviors.
- For additional information, contact the Northeast Division of Migratory Birds, Permit Branch, Eagle Coordinator. Contact information for the USFWS Northeast Division of Migratory Birds can be found at: https://www.fws.gov/northeast/migratorybirds/contactus.html.

Will you implement the above measures? ☐ Yes ☐ No

If these measures cannot be implemented, then you must contact the Service's Migratory Bird Permit Office.

- Permit Office for District of Columbia, Delaware, Maryland, New Jersey, New York, Pennsylvania, Virginia, West Virginia: (413) 253-8643 or by email: permitsR5MB@fws.gov
- Permit Office for North Carolina: (404) 679-7070 or by email: permitsR4MB@fws.gov

L. MIGRATORY BIRDS
(Optional to complete prior to Emergency Consultation)

Shorebirds, coastal marsh birds, and marine birds can be found throughout the coastal zone. In accordance with the Migratory Bird Treaty Act of 1918 (as amended) and Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 et seq.), please be advised that proposed response actions may be located in habitats which are commonly inhabited by these important species.

Although several surveys have been conducted to determine the location of nesting colonies, the USFWS recommends that a qualified biologist inspect the proposed response area for the presence of nesting colonies during the nesting season since they may change locations year-to-year.

- For general information regarding migratory birds: https://www.fws.gov/northeast/migratorybirds/.
- For information regarding which bird species may be present in the area, please visit: https://ebird.org/explore.
- For USFWS general conservation measures to avoid and minimize impacts to birds: https://www.fws.gov/birds/management/project-assessment-tools-and-guidance/conservation-measures.php
- The Mid-Atlantic coast provides critical year-round habitats for shorebirds and is part of the Atlantic Flyway. The most important habitats are the outer coastal strand of beaches, inlets, tidal flats, and saltmarsh. Providing and maintaining quality nesting, migration stopover, and wintering sites in the southeastern U.S. is extremely important for population health and stability of Atlantic Flyway shorebird populations. The focal geographic area includes the important spring staging sites of Delaware Bay, and large areas of undeveloped barrier islands and saltmarshes extending from Virginia to Georgia. Atlantic Flyway Shorebird species include the American Oystercatcher, American Golden-Plover, Snowy Plover, Wilson's Plover, Marbled Godwit, Ruddy Turnstone, Red Knot, Sanderling, Piping Plover, Greater Yellowlegs,

L. MIGRATORY BIRDS
(Optional to complete prior to Emergency Consultation)

Lesser Yellowlegs, Whimbrel, Purple Sandpiper, Semipalmated Sandpiper, Red-necked Phalarope, or Eskimo Curlew. The Atlantic Flyway Shorebird Initiative focuses on these birds: https://atlanticflywayshorebirds.org/.

- Tidal marsh birds such as the Saltmarsh Sparrow, Black Rail, American Black Duck, Bicknell's Thrush, Cerulean Warbler, Wood Thrush, Golden-winged Warbler, American Woodcock, and the coastal marsh habitat they inhabit are a focus for USFWS. The Atlantic Coast Joint Venture (ACJV) focuses on these birds: https://acjv.org/.
- Marine birds are also a focal species for management and monitoring, which include colonial waterbirds, as well as nesting shorebirds. The Atlantic Marine Bird Cooperative (AMBC) focuses on these birds: https://atlanticmarinebirds.org/.
- If the USCG would like to report any banded birds observed during response actions to aid in resighting efforts, reporting can be done here: https://www.usgs.gov/centers/pwrc/science/bird-banding-laboratory.
- Contact information for the USFWS Northeast Division of Migratory Birds can be found at: https://www.fws.gov/northeast/migratorybirds/contactus.html.

Will you implement conservation measures for shorebirds, coastal marsh birds, and marine birds (indicate which species may be present)?

☐ Yes Enter list of bird species.

☐ No Indicate why conservation measures will not be implemented.

☐ Not Applicable (i.e., not present in the action area)

M. SUBMITTING BIOLOGICAL EVALUATION (BE) FORM

The USFWS and NMFS request that all BE forms be emailed to the appropriate point of contact for review (see Enclosure 1 for list of contacts). Upon receipt, USFWS/NMFS representatives will conduct a preliminary review and provide any comments and feedback, including any requests for modifications or additional information. If modifications or additional information is necessary, USFWS/NMFS representative will work with the USCG until the BE form is considered complete. Once complete, the USCG will use the BE form to initiate and/or conduct any appropriate consultation.

For informational purposes, please add the **U.S. Dept. of the Interior's (DOI) Regional Environmental Officer (REO)** and the **NOAA Scientific Support Coordinator (SSC)** assigned to the incident to the "Cc" line of your email when submitting any version of this form to the USFWS and NMFS for review and/or concurrence. **Additionally**, please also "Cc" the Fifth District Response Advisory Team (DRAT) David.E.Pugh1@uscg.mil and Elisha.FS.Cook@uscg.mil to your email when submitting any version of this form to the USFWS and NMFS for review and/or concurrence. Also "Cc" the appropriate Environmental Protection Agency (EPA) Region 3 or 4 On-scene Coordinator.

RRT 3 ESA EFH Section 7

Coastal Zone Consult Form (Only)

ENCLOSURE 2: ESA SECTION 7 / EFH CONSULTATION FORM

This form will be utilized by the U.S. Coast Guard (USCG) Federal On-Scene Coordinator (FOSC) for pre-spill, emergency, and post-response Endangered Species Act (ESA) Section 7 consultations. It will be filled out by the USCG and used by the Department of the Interior's (DOI) U.S. Fish & Wildlife Service (USFWS) and the National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS) to review response actions for potential impacts to federally listed species. The form provides information to initiate and conclude emergency consultations under ESA §7 and to document (1) a "No Effect" determination, (2) to request technical assistance, or (3) to document up to the May Affect, Not Likely to Adversely Affect threshold. Additionally, information beyond this form may be required by the Services.

FOSCs (or their designated representative) should complete Section I after initial notification is made to the Services. Section I should be filled out with the best available information accounting for all response actions taken or being considered. For emergency consultations, only tables A – E must be completed prior to forwarding to the Services. FOSCs may work with Service representatives during the emergency consultation process to determine the presence and effects to species/habitats and implementation of conservation measures in Tables F - L. **Section II is intended to be submitted blank to the Services, so the Services can both acknowledge the request for consultation as well as begin to consider the FOSC's actions or proposed actions during the emergency response.** This form should also be used to provide updates to the Services as the incident evolves and FOSC actions are adjusted based on operational objectives. When needed and applicable, this form will also be completed to inform and evaluate additional needs for compliance with the following authorities: Magnuson-Stevens Fishery Conservation and Management Act (for Essential Fish Habitat [EFH]), Migratory Bird Treaty Act (MBTA), Marine Mammal Protection Act (MMPA), Coastal Barrier Resources Act (CBRA), Bald and Golden Eagle Protection Act (BGEPA).

E. RESPONSE ACTION AREA / HABITAT TYPES

Provide a description of the existing environment (e.g., vegetation type, substrate type, tidal/riverine/estuarine, hydrology and drainage patterns, current flow and direction) and land uses (e.g., public, residential, commercial, industrial, agricultural). Describe all areas that may be directly or indirectly affected by the response action(s). If possible, provide name of waterbody in the "Details / Notes" column.

The information provided in this section will be used in both ESA Emergency Consultation and Essential Fish Habitat (EFH) analyses, so please provide additional information to the maximum extent practicable, particularly if there is an EFH Habitat Areas of Particular Concern (HAPC) that may be found in the response action area. The Essential Fish Habitat Mapper tool may be used to identify EFH and/or HAPCs in the action area: https://www.habitat.noaa.gov/apps/efhmapper/efhreport/

F. NMFS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED

(Optional to complete prior to Emergency Consultation)

Identify all species and critical habitat under NMFS jurisdiction that may be found in the response action area.

- For Sector Delaware Bay, Maryland-NCR, or Virginia refer to the Greater Atlantic Region ESA Section 7 Mapper to identify ESA-listed species and critical habitat in the action area: https://www.fisheries.noaa.gov/new-england-mid-atlantic/consultations/section-7-species-critical-habitat-information-maps-greater
- For Sector North Carolina refer to the South Atlantic Species and Critical Habitat List: https://www.fisheries.noaa.gov/southeast/consultations/north-carolina

If all consequences of proposed response actions occur in a location that does not contain any listed or proposed NMFS species or designated/proposed critical habitats, OR if those response actions and their effects have been covered under previous existing consultations, please check the appropriate box below. If one of these boxes is checked, you may skip this section.

F. NMFS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

☐ All direct and indirect effects of the proposed response actions occur in a location that does not contain any listed or proposed NMFS species or designated/proposed critical habitats.

☐ All direct and indirect effects of the proposed response actions have been accounted for under an existing ESA Section 7 consultation.

Determination Definitions (applicable to both species and designated critical habitat determinations):

NE = no effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed or proposed species or designated/proposed critical habitat.

NLAA = may affect, not likely to adversely affect. This determination is appropriate when the proposed action is not likely to adversely impact any listed or proposed species or designated/proposed critical habitat, or there may be beneficial effects to these resources. The USCG would request the Services to concur with the not likely to adversely affect determination. This conclusion is appropriate when effects to the species or critical habitat will be wholly beneficial, discountable, or insignificant. Beneficial effects are contemporaneous positive effects without any adverse effects to the species or habitat. Insignificant effects relate to the size of the impact, while discountable effects are those that are extremely unlikely to occur. Based on best judgment, a person would not: (1) be able to meaningfully measure, detect, or evaluate insignificant effects; or (2) expect discountable effects to occur. If the Services concur in writing with the Action Agency's determination of "is not likely to adversely affect" listed species or critical habitat, the §7 consultation process is completed.

LAA = may affect, likely to adversely affect. This determination is appropriate when the proposed action is likely to adversely impact any listed or proposed species or designated/proposed critical habitat. The USCG would request formal

F. NMFS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

consultation with the Services for a response action(s) with a likely to adversely affect determination; the Services' response would be a biological opinion as the concluding document. This conclusion is reached if any adverse effect to listed species or critical habitat may occur as a direct or indirect result of the proposed action or its cumulative effects, and the effect is not discountable or insignificant. In the event the overall effect of the proposed action is beneficial to the listed species or critical habitat but may also cause some adverse effect on individuals of the listed species or segments of the critical habitat, then the determination is "likely to adversely affect." Any LAA determination requires formal §7 consultation and will require additional information.

G. USFWS THREATENED / ENDANGERED SPECIES & CRITICAL HABITAT EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

Identify all species and critical habitat under USFWS jurisdiction that may be found in the response action area.

- The USFWS Information for Planning and Consultation (IPaC) tool may be used to identify ESA-listed species and critical habitat in the action area: https://ecos.fws.gov/ipac/

If all consequences of proposed response actions occur in a location that does not contain any listed or proposed USFWS species or designated/proposed critical habitats, OR if those response actions and their effects have been covered under previous existing consultations, please check the appropriate box below. If one of these boxes is checked, you may skip this section.

☐ All direct and indirect effects of the proposed response actions occur in a location that does not contain any listed or proposed USFWS species or designated/proposed critical habitats.

☐ All direct and indirect effects of the proposed response actions have been accounted for under an existing ESA Section 7 consultation.

If the Services concur in writing with the Action Agency's determination of "is not likely to adversely affect" listed species or critical habitat, the §7 consultation process is completed.

LAA = may affect, likely to adversely affect. This determination is appropriate when the proposed action is likely to adversely impact any listed or proposed species or designated/proposed critical habitat. The USCG would request formal consultation with the Services for a response action(s) with a likely to adversely affect determination; the Services' response would be a biological opinion as the concluding document. This conclusion is reached if any adverse effect to listed species or critical habitat may occur as a direct or indirect result of the proposed action or its cumulative effects, and the effect is not discountable or insignificant. In the event the overall effect of the proposed action is beneficial to the listed species or critical habitat but may also cause some adverse effect on individuals of the listed species or segments of the critical habitat, then the determination is "likely to adversely affect." Any LAA determination requires formal §7 consultation and will require additional information.

H. ESSENTIAL FISH HABITAT AREAS OF PARTICULAR CONCERN EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

Identify all EFH species and Habitat Areas of Particular Concern (HAPC) that may be found in the response action area.

- The Essential Fish Habitat Mapper tool may be used to identify EFH and/or HAPCs in the action area: https://www.habitat.noaa.gov/apps/efhmapper/efhreport/

If all consequences of proposed response actions occur in a location that does not contain any EFH species or HAPCs, OR if those response actions and their effects have been covered under previous existing consultations, please check the appropriate box below. If one of these boxes is checked, you may skip this section.

☐ All direct and indirect effects of the proposed response actions occur in a location that does not contain any EFH species or HAPCs.

H. ESSENTIAL FISH HABITAT AREAS OF PARTICULAR CONCERN EFFECTS DETERMINATION REQUESTED
(Optional to complete prior to Emergency Consultation)

☐ All direct and indirect effects of the proposed response actions have been accounted for under an existing EFH consultation.

☐ List species.	☐	Select a determination.	Select most appropriate.
☐ List species.	☐	Select a determination.	Select most appropriate.

Determination Definitions (applicable to both EFH and HAPC determinations):
WNAA = would not adversely affect. Would not adversely affect is the appropriate determination if the response action and the stressors of that action would not affect EFH.
MAA = may adversely affect. Adverse Effects are anything that changes the quality or quantity of EFH.

I. EFFECTS OF RESPONSE ACTIONS & MEASURES TO REDUCE IMPACTS TO LISTED SPECIES AND CRITICAL HABITATS
(Optional to complete prior to Emergency Consultation)

Explain the potential beneficial and adverse effects to each species and/or critical habitats identified in the above tables.

Describe what, when, and how the species and/or critical habitat will be impacted and the likely response to the impact. Be sure to include direct, indirect, and cumulative impacts, and where possible, quantify those effects. If species are present (or potentially present) and will not be adversely affected, describe your rationale. If species are unlikely to be present in the general area or action area, explain why. Describe your

I. EFFECTS OF RESPONSE ACTIONS & MEASURES TO REDUCE IMPACTS TO LISTED SPECIES AND CRITICAL HABITATS
(Optional to complete prior to Emergency Consultation)

rationale if designated or proposed critical habitats are present and will not be adversely affected. This justification provides documentation for your administrative record, avoids the need for additional correspondence, and helps expedite review.

NOTE: Species selected as "No Effect" with justification in the above tables do not need to be addressed.

Click or tap here to enter text.

Explain the measures taken to reduce adverse effects to the species identified above.

For each species for which impacts were identified, describe any conservation measures (e.g., best management practices [BMPs]) that will be implemented to avoid or minimize the impacts. Conservation measures are designed to avoid or minimize effects to listed species and critical habitats or further the recovery of the species under review. Conservation measures are considered part of the proposed actions and their implementation is required. Any changes to, modifications of, or failure to implement these conservation measures may result in a need to reinitiate this consultation.

Click or tap here to enter text.

Frequently Recommended BMPs

This checklist provides standard BMPs recommended by NMFS and USFWS or developed in coordination with the Services. Please select any BMPs that will be implemented (website links to BMPs are provided below).

☐ Environmental BMPs for Oil Spill Response in Regional Response Team 3 Coastal Zone	[placeholder for link to document on RRT III website]
☐ NMFS EFH BMPs for Certain Response Activities to Accidental Discharges of Oil and Other Hazardous Materials in the Southeastern United States	https://media.fisheries.noaa.gov/dam-migration/sero_hazmat_bmps.pdf
☐ NMFS Marine Life Viewing Guidelines and Distances	https://www.fisheries.noaa.gov/topic/marine-life-viewing-guidelines#guidelines-&-distances
☐ NMFS Measures for Reducing the Entrapment Risk to Protected Species	https://media.fisheries.noaa.gov/dam-migration/entrapment_bmps_final.pdf
☐ NMFS Sea Turtle Handling and Resuscitation Requirements	https://media.fisheries.noaa.gov/dam-migration/sea_turtle_handling_and_resuscitation_measures.pdf
☐ NMFS Sturgeon Resuscitation Guidelines	https://media.fisheries.noaa.gov/dam-migration/sturgeon_resuscitation_card_06122020_508.pdf
☐ NMFS Vessel Strike Avoidance Measures and Reporting for Mariners	https://media.fisheries.noaa.gov/dam-migration/vessel_strike_avoidance_february_2008.pdf
☐ USFWS Avoidance and Minimization Measures for Piping Plover and Red Knot for Shoreline Activities	https://www.fws.gov/southeast/pdf/best-management-practice/piping-plover-and-red-knots-for-shoreline-activities-in-louisiana.pdf

I. EFFECTS OF RESPONSE ACTIONS & MEASURES TO REDUCE IMPACTS TO LISTED SPECIES AND CRITICAL HABITATS (Optional to complete prior to Emergency Consultation)	
☐ USFWS Standard Manatee In-Water Conditions	https://www.fws.gov/southeast/pdf/guidelines/standard-manatee-conditions.pdf
☐ National Response Team General BMPs or Conservation Measures (Appendix D)	https://www.nrt.org/sites/2/files/Pre-Spill_BEOutline_%20updated%2031Oct2018%20FINAL.docx
☐ Caribbean Regional Response Team BMPs for Oil Spill Response Operations	https://nrt.org/sites/33/files/App%207%20CRRT%20Compilation%20of%20BMPs%20Revised% 204_2020.pdf
☐ OTHER (list below) Name of BMP.	Provide a link to BMP.

J. MARINE MAMMALS
(Optional to complete prior to Emergency Consultation)

The Marine Mammal Protection Act (MMPA) prohibits the taking (including disruption of behavior, entrapment, injury, or death) of all marine mammals. The MMPA allows limited exceptions to the take prohibition, if authorized, such as the incidental take of marine mammals. The Atlantic Marine Assessment Program for Protected Species (AMAPPS) Marine Mammal Model Viewer (https://apps-nefsc.fisheries.noaa.gov/AMAPPSviewer/) maps marine life sightings and ocean conditions to help inform marine resource management decisions. The maps use whale, dolphin, and porpoise sightings data and can be sued to predict marine mammal densities.

Marine Mammals that *may be* present within the response action area	**Details / Notes** (If applicable, indicate and describe the species that may be present in the response action area)
Dolphins ☐ Yes ☐ No	Click or tap here to enter text.
Manatees ☐ Yes ☐ No	Click or tap here to enter text.
Porpoise ☐ Yes ☐ No	Click or tap here to enter text.
Seals ☐ Yes ☐ No	Click or tap here to enter text.
Whales ☐ Yes ☐ No	Click or tap here to enter text.

The following questions are designed to allow the NMFS and/or USFWS to quickly determine if response actions have the potential to result in take to marine mammals. If the information provided indicates that incidental take is possible, further discussion with the NMFS and/or USFWS is required.

(a) Is your action occurring in or on marine or estuarine waters? ☐ Yes ☐ No

(b) If yes, is your action likely to cause large-scale, ecosystem level impacts to the quality (e.g., salinity, temperature) of marine or estuarine waters? ☐ Yes ☐ No

(c) If yes, describe actions further using checkboxes in the table below. Does your action involve any of the following:

J. MARINE MAMMALS
(Optional to complete prior to Emergency Consultation)

☐ Yes ☐ No	Use of active acoustic equipment (e.g., echosounder) producing sound below 200 kHz
☐ Yes ☐ No	In-water construction or demolition
☐ Yes ☐ No	Temporary or fixed use of active or passive sampling gear (e.g., nets, lines, traps; turtle relocation trawls)
☐ Yes ☐ No	In-water explosive detonation
☐ Yes ☐ No	Aquaculture
☐ Yes ☐ No	Restoration of barrier islands, levee construction, or similar projects
☐ Yes ☐ No	Fresh-water river diversions
☐ Yes ☐ No	Building or enhancing areas for water-related recreational use or fishing opportunities (e.g., fishing piers, bridges, boat ramps, marinas)
☐ Yes ☐ No	Dredging or in-water construction actions to change hydrologic conditions or connectivity, create breakwaters and living shorelines, etc.
☐ Yes ☐ No	Conducting driving of sheet piles or pilings
☐ Yes ☐ No	Use of floating pipeline during dredging actions

If you checked "Yes" to any of the actions immediately above, or if the action *could impact* the quality of marine or estuarine waters, please describe the nature of the actions in more detail or indicate which section of the form already includes these descriptions.

Click or tap here to enter text.

If not already identified in Table I, please describe any additional BMPs or conservation measure that may be implemented for marine mammals.

☐ OTHER (list below) Name of BMP.	Provide a link to BMP.
☐ OTHER (list below) Name of BMP.	Provide a link to BMP.

K. BALD EAGLES
(Optional to complete prior to Emergency Consultation)

Are bald eagles present in the response area? ☐ Yes ☐ No

If YES, the following conservation measures should be implemented per the National Bald Eagle Management Guidelines: https://www.fws.gov/northeast/ecologicalservices/eagle.html

- If bald eagle breeding or nesting behaviors are observed or a nest is discovered or known, all actions (e.g., walking, camping, clean-up, use of a UTV, ATV, or boat) should avoid the nest by a minimum of 660 feet. If the nest is protected by a vegetated buffer where there is no line of sight to the nest, then the minimum avoidance distance is 330 feet. This avoidance distance shall be maintained from the onset of breeding/courtship behaviors until any eggs have hatched and eaglets have fledged (approximately 6 months).
- If a similar action (e.g., driving on a roadway) is closer than 660 feet to a nest, then you may maintain a distance buffer as close to the nest as the existing tolerated action.

K. BALD EAGLES
(Optional to complete prior to Emergency Consultation)

- If a vegetated buffer is present and there is no line of sight to the nest and a similar action is closer than 330 feet to a nest, then you may maintain a distance buffer as close to the nest as the existing tolerated action.
- In some instances, actions conducted at a distance greater than 660 feet of a nest may result in disturbance. If an action appears to cause initial disturbance, the action shall stop and all individuals and equipment will be moved away until the eagles are no longer displaying disturbance behaviors.
- For additional information, contact the Northeast Division of Migratory Birds, Permit Branch, Eagle Coordinator. Contact information for the USFWS Northeast Division of Migratory Birds can be found at: https://www.fws.gov/northeast/migratorybirds/contactus.html.

Will you implement the above measures? ☐ Yes ☐ No

If these measures cannot be implemented, then you must contact the Service's Migratory Bird Permit Office.

- Permit Office for District of Columbia, Delaware, Maryland, New Jersey, New York, Pennsylvania, Virginia, West Virginia: (413) 253-8643 or by email: permitsR5MB@fws.gov
- Permit Office for North Carolina: (404) 679-7070 or by email: permitsR4MB@fws.gov

L. MIGRATORY BIRDS
(Optional to complete prior to Emergency Consultation)

Shorebirds, coastal marsh birds, and marine birds can be found throughout the coastal zone. In accordance with the Migratory Bird Treaty Act of 1918 (as amended) and Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 et seq.), please be advised that proposed response actions may be located in habitats which are commonly inhabited by these important species.

Although several surveys have been conducted to determine the location of nesting colonies, the USFWS recommends that a qualified biologist inspect the proposed response area for the presence of nesting colonies during the nesting season since they may change locations year-to-year.

- For general information regarding migratory birds: https://www.fws.gov/northeast/migratorybirds/.
- For information regarding which bird species may be present in the area, please visit: https://ebird.org/explore.
- For USFWS general conservation measures to avoid and minimize impacts to birds: https://www.fws.gov/birds/management/project-assessment-tools-and-guidance/conservation-measures.php
- The Mid-Atlantic coast provides critical year-round habitats for shorebirds and is part of the Atlantic Flyway. The most important habitats are the outer coastal strand of beaches, inlets, tidal flats, and saltmarsh. Providing and maintaining quality nesting, migration stopover, and wintering sites in the southeastern U.S. is extremely important for population health and stability of Atlantic Flyway shorebird populations. The focal geographic area includes the important spring staging sites of Delaware Bay, and large areas of undeveloped barrier islands and saltmarshes extending from Virginia to Georgia. Atlantic Flyway Shorebird species include the American Oystercatcher, American Golden-Plover, Snowy Plover, Wilson's Plover, Marbled Godwit, Ruddy Turnstone, Red Knot, Sanderling, Piping Plover, Greater Yellowlegs,

L. MIGRATORY BIRDS
(Optional to complete prior to Emergency Consultation)

Lesser Yellowlegs, Whimbrel, Purple Sandpiper, Semipalmated Sandpiper, Red-necked Phalarope, or Eskimo Curlew. The Atlantic Flyway Shorebird Initiative focuses on these birds: https://atlanticflywayshorebirds.org/.

- Tidal marsh birds such as the Saltmarsh Sparrow, Black Rail, American Black Duck, Bicknell's Thrush, Cerulean Warbler, Wood Thrush, Golden-winged Warbler, American Woodcock, and the coastal marsh habitat they inhabit are a focus for USFWS. The Atlantic Coast Joint Venture (ACJV) focuses on these birds: https://acjv.org/.
- Marine birds are also a focal species for management and monitoring, which include colonial waterbirds, as well as nesting shorebirds. The Atlantic Marine Bird Cooperative (AMBC) focuses on these birds: https://atlanticmarinebirds.org/.
- If the USCG would like to report any banded birds observed during response actions to aid in resighting efforts, reporting can be done here: https://www.usgs.gov/centers/pwrc/science/bird-banding-laboratory.
- Contact information for the USFWS Northeast Division of Migratory Birds can be found at: https://www.fws.gov/northeast/migratorybirds/contactus.html.

Will you implement conservation measures for shorebirds, coastal marsh birds, and marine birds (indicate which species may be present)?

☐ Yes Enter list of bird species.

☐ No Indicate why conservation measures will not be implemented.

☐ Not Applicable (i.e., not present in the action area)

M. SUBMITTING BIOLOGICAL EVALUATION (BE) FORM

The USFWS and NMFS request that all BE forms be emailed to the appropriate point of contact for review (see Enclosure 1 for list of contacts). Upon receipt, USFWS/NMFS representatives will conduct a preliminary review and provide any comments and feedback, including any requests for modifications or additional information. If modifications or additional information is necessary, USFWS/NMFS representative will work with the USCG until the BE form is considered complete. Once complete, the USCG will use the BE form to initiate and/or conduct any appropriate consultation.

For informational purposes, please add the **U.S. Dept. of the Interior's (DOI) Regional Environmental Officer (REO)** and the **NOAA Scientific Support Coordinator (SSC)** assigned to the incident to the "Cc" line of your email when submitting any version of this form to the USFWS and NMFS for review and/or concurrence. **Additionally**, please also "Cc" the Fifth District Response Advisory Team (DRAT) David.E.Pugh1@uscg.mil and Elisha.FS.Cook@uscg.mil to your email when submitting any version of this form to the USFWS and NMFS for review and/or concurrence. Also "Cc" the appropriate Environmental Protection Agency (EPA) Region 3 or 4 On-scene Coordinator.

Significant Spills In SecDelBay AOR

Significant* Oil Spill Events in Delaware River and Bay

Responsible Party	Date	Amount Spilled	Product Spilled
M/T *Elias* – ARCO, Ft. Mifflin Dock	9 April 1974	12,000 bbl of a 217,000 bbl cargo	***Bachaquero crude oil explosion, fire, spill
T/V *Corinthos* – Marcus Hook	31 Jan 1975	266,000 barrels	Fire and crude oil spill while docked at BP *Edgar M. Queeny* collided with *Corinthos*
T/V *Grand Eagle*	29 Sept 1985	435,000 gallons	Crude oil **- g**rounded MH Bar
Coastal Eagle Point	5 Dec 1985	22,000 gallons 80 tons	Benzene
Standard Chlorine	3 Jan 1986	569,000 gallons	PDCB/benzene
T/V *Intermar Alliance*	21 Mar 1986	189,000 gallons	Nigerian/Ninian Crude loss of steerage
T/V *Viking Osprey*	8 Sept 1986	295,000 gallons	Bottom scrap Marcus Hook Bar –Claymont Shoal
M/V *Jahre Spray*	7 Oct 1988	Trailing sheen - 6 miles	Nigerian crude oil
T/V *Presidente Rivera* –South of Marcus Hook	24 June 1989	435,000 gallons	#6 heavy oil – industrial grade – grounding Claymont Shoal
Barge *Worlds Radiance* – Hogg Island Terminal	21 Nov 1989	4200 gallons	Storm - Barge broke from dock while off loading – crude oil
T/V *Faith I & Ocean Barge 190*	19 Aug 1990	168,000 gallons	Gasoline **-** collision
M/V *Santa Clara* 30 miles off Cape May	3 Jan 1992	Containers	Arsenic Trioxide –containers weather
M/V *Kentucky*	22 July 1994	13,000 gallons	Crude oil – suspected grounding Marcus Hook bar-Claymont Shoal
M/V *Jahre Spray* Eagle Point Refinery	22 July 1995	56,000 gallons	West African Rabbi crude –transfer hose broke during storm
T/V *Anitra* Big Stone Anchorage	9 May 1996	42,000 gallons	Nemba and Cabinda light crude oils. Leak below water line.
Bouchard *Barge 155* Bombay Hook Anchorage	24 Oct 1996	2,000 gallons	#6 fuel from Anchor compartment while waiting out storm
T/V *Niki* - Delaware City	1996	1,500 gallons	
M/V *Mystras* - Big Stone Anchorage	18 Sep 1997	200 bbls (8,400 gallons)	Brent crude oil
Bouchard *Barge #115*- Motiva	27 Oct 1999	6,300 gallons	Vacuum gas oil - overfill
Conectiv/IRPP	Dec 1999	750,000 gallons	subsurface diesel spill
Tug John Terecamo Near Ft. Mifflin	15 June 2001	2,000 gallons	Hit by propeller of Tanker –grounded to avoid sinking. Diesel fuel
Motiva Acid Spill Delaware City	17 July 2001-	Land based spill- 10,000 gallons to water	Spent sulfuric acid and water mixture – fire/explosion
T/V *Athos I* – Vicinity of CITGO docks, Paulsboro. NJ	26 Nov 2004	265,000 gallons	Crude oil – heavy Hit submerged objects
M/V *Bermuda Islander*	26 April 2006	Original mystery spill- ? gals	Oil trailing six miles

IPC Spill- Christina River, Wilmington	15 July 2006	2,100 gal	Waste oil – land based tank/line leak
T/V *Tigani* CITGO Dock	7 Oct 2007	1,600 gallons	#6 Bunker C oil – cracked scupper line that passed through a bunker tank – leaking while docked
Sunken Tugs - Schuylkill River	29 July 2008	1,200 gallons?	fuel oil/waste oil spill

*"Significant" is a relative term that is used in the title to mean amount spilled, level of response or the notoriety of the event.

***The petroleum industry generally classifies crude oil:
By the geographic location it is produced in (e.g. West Texas Intermediate, Brent),
Its API (American Petroleum Institute) gravity (an oil industry measure of density),
and by its sulfur content.

Crude oil may be considered *light* if it has low density or *heavy* if it has high density; and it may be referred to as sweet if it contains relatively little sulfur or *sour* if it contains substantial amounts of sulfur.

Brent and Ninian crude come from the North Sea area.
Nemba and Cabinda light crude oils are produced in Angola.
Nigerian crude oil could be Bonny Light, Agbami (light, sweet),
Escravos or Pennington. Bachaquero crude oil is from Venezuela.

Introduction

Oil is a complex and variable natural substance. When released into the sea it can be transported long distances, undergo various physical and chemical changes, and adversely affect marine ecosystems. Oil's fate and effects depend on the type and quantity of oil spilled, properties of the oil as modified over time by physical and chemical processes, the organisms and habitats exposed, and the nature of the exposure. All of these factors should be considered when evaluating response methods. Interactions among these variables result in a large range of spill situations. Accordingly, spill responders must determine the combination of response methods that best suits the spill situation.

Response techniques have "windows of opportunity," specific timeframes when each response method works the best. These windows are defined by the type of product spilled, the initial spill conditions, product weathering and emulsion rates, and the very different environments and ecosystems that are, or will be, impacted. When the methods are used within these windows, they are more effective and less damaging to habitats and populations that survive the oil, reducing the time affected ecosystems need to recover.

In every oil spill, government and industry decision-makers are presented with a unique set of challenges requiring timely application of appropriate response methods. Two important questions that must be considered are:

- How does an on-scene coordinator or a responsible party sort through the myriad of options and select those methods that will effectively mitigate and clean up the oil?
- What is the rationale for selection?

Characteristics of Response Strategies addresses these questions by providing information to decision-makers relating to tradeoff decisions for specific habitats and response options. It focuses on maximizing response effectiveness while minimizing resource impacts.

Remember that the selection of a proper response method is highly dependent on incident-specific conditions, and that the strengths and weaknesses of a given response tool affect the suitability for its employment in a given habitat for a

specific spill. Accordingly, using multiple methods simultaneously throughout an incident can produce a more effective response and minimize environmental impacts.

Selecting response options, including natural recovery, involves considering tradeoffs among their potential environmental impact, appropriateness for habitat, and application timing.

The 2001 *Characteristics of Response Strategies* and its companion guide, *Characteristic Coastal Habitats: Choosing Spill Response Alternatives* (NOAA 2000), were based on information contained in *Environmental Considerations for Marine Oil Spill Response*, published by the American Petroleum Institute, National Oceanic and Atmospheric Administration, the U.S. Coast Guard, and the U.S. Environmental Protection Agency. The 2010 revisions incorporates new information learned from spill response and research since the original publication.

Characteristics of Response Strategies is a useful aid for informing people who will be participating in cleanup assessments as part of Operations and Planning Units within the Incident Command System.

How to Use this Document

This document summarizes the technical rational for selecting response methods. A companion guide to *Environmental Considerations for Marine Oil Spill Response*, *Characteristics of Response Strategies* can help you select appropriate response options to minimize adverse environmental impacts of a marine oil spill. The guide discusses developing incident-specific strategies and describes the characteristics of individual response methods. Response methods include natural recovery, mechanical, chemical, and biological treatments; and in-situ burning.

When choosing effective response options including natural recovery, you must consider trade-offs affecting the options' potential environmental impact, their appropriateness for the habitat, and the timing of the application. *Environmental Considerations for Marine Oil Spill Response* discusses these considerations in detail; consult it before using this guideline. Remember, the benefits and impacts of response options depend upon incident-specific conditions and affect the options' suitability for use in a habitat during any spill.

This guide includes information about response methods now used during oil spill responses in marine environment. It provides guidelines for developing response actions, evaluating incident-specific feasibility issues for both on-water and shoreline environments, and developing incident-specific strategies.

The final section of this guide includes detailed descriptions of the response methods now in use during oil spill responses in marine environments. These descriptions begin on page 38 with Natural Recovery.

Strategies for Selecting Response Methods

During emergency response operations, available information may be highly uncertain and fragmented at best, as will forecasts of environmental conditions or evaluations of response equipment needs. Nonetheless, the response community must sort out what is actually known about the spill, and select and deploy equipment as soon and as effectively as possible. What information is needed to help guide the response? What can be done to promote any gains in environmental protection?

Because the goal of oil spill response is to minimize the overall impacts on natural and economic resources, some resources will be of greater concern than others; and response options offering different degrees of resource protection will be selected accordingly. Decisions regarding cleanup method(s) must balance two factors: 1) the potential environmental impacts with the natural recovery alternative, and 2) the potential environmental impacts associated with a response method or group of methods.

Potential impacts can be determined before considering the need for, or type of, response strategies. For example, evaluating a gasoline spill in an exposed seawall environment might lead to the conclusion that, due to evaporation and low habitat use, minimal environmental effects will occur and further evaluation is unwarranted. On the other hand, assessing a spill of a middle-weight crude oil in a soft intertidal area would likely indicate a high potential for environmental effects; therefore, response methods would need to be evaluated.

The decisions to select response methods should consider the potential of each possible method for reducing the environmental consequences of the spill and the response (including a natural recovery alternative). The method, or combination of methods, that most reduces consequences effectively, should be the preferred response strategy. A method that increases impacts in the short term can be the preferred alternative if it speeds up recovery. (Recovery cannot be defined as pre-spill conditions since natural changes in biological communities will introduce variability to organisms affected by the spill.)

The environmental consequences of a spill and the response will depend on the specific spill conditions, such as the type and amount of oil, weather conditions, habitat where the spill occurred, and effectiveness of the response methods. It is imperative that planners and responders discuss and develop resource protection priorities during contingency planning so that valuable time is not lost during an actual response. Area Contingency Plans (ACPs) and Geographic Response Plans (GRPs) are essential to an effective response.

Guidelines for Developing Response Actions

This document provides information to help the reader understand the trade-offs that were considered in developing the *Environmental Considerations for Marine Oil Spill Response* (API et al., 2001) and the *Characteristics of Coastal Habitats* (NOAA, 2010). These companion documents reflect a consensus of extensive, technically appropriate, pre-spill decision processes regarding response:

- **Goals** (overall aims of the response, defined by government);
- **Objectives** (specified response outcomes, defined by response management and in support of the Goals);
- **Strategies** (plans used to carry out objectives, protect resources at risk);
- **Tactics** (specific actions taken to carry out a strategy); and
- **Windows of opportunity** (time-frame during which response actions are viable or most effective).

Goals

Generally, oil spill response goals, in order of priority, are:

1. Ensure safety of human life;
2. Stabilize the situation to preclude it from worsening (e.g., source control, on-water recovery); and
3. Minimize adverse environmental and socioeconomic impacts.

Objectives

Responders should develop incident-specific, and sometimes geographically specific, objectives and strategies to address all three goals simultaneously. While attaining the first two goals, responders must develop incident-specific response objectives that achieve the third goal to minimize further spill impacts and protect resources at risk. Objectives must be clearly articulated and be measurable and achievable (e.g., prevent oil from reaching a specific part of the shoreline from another area). Effectively planning and executing a response requires a framework within which limited response resources (people, equipment, time) can be allocated to protect multiple resources at risk. Not all of these can be protected; some will have higher priorities than others for protection.

Strategies

Strategies are the conceptual plans designed to achieve response objectives. For example, a combination of mechanical containment and recovery equipment, dispersants, and in-situ burning can prevent oil from affecting sensitive on-water and nearshore resources and from reaching the shoreline.

Initial spill conditions will play a large role in developing an effective strategy. Sufficient initial information must be gathered to determine:

- Type and amount of oil spilled;
- Spill location;
- Behavior of spilled oil;
- Spill trajectories and persistence;
- Locations and resources that may be impacted, and types of impacts; and
- Current and forecast weather.

As information is gathered, strategies can be developed (and revised as conditions change) to protect those resources at risk. Though response strategies will vary according to incident-specific conditions, strategies can often be established in spill response planning (such as Area Contingency Plans, Geographic Response Plans, Facility and Vessel Response Plans, and the like), consistent with response goals.

Tactics

Tactics are site-specific individual activities taken to implement strategies. They can also be established in spill response plans, consistent with response goals. Specific tactics are usually developed for 12- to 24-hour time periods, however they can be extended as the Operational Period changes.

Windows of Opportunity

Windows of opportunity (time-frames during which response actions are viable) are constrained or bound by certain influences or conditions, and are available or "open" for limited times.

Three primary windows exist following a marine oil spill. Within each window, certain spill control measures can be taken to minimize adverse environmental effects:

1. **Very early** - Oil is fresh and concentrated near the discharge source.
    - Window may be open for 1–2 days; and
    - Responders focus on source control, containment near the source, and removal (these offer the best opportunities to reduce adverse environmental impacts).
2. **Early** - Oil has spread, is no longer concentrated, and threatens sensitive resources and habitats.
    - Window may be open for several days to weeks;
    - Sensitive resources and habitats are threatened; and
    - Responders work to minimize the spread of oil, prevent it from contacting resources at risk, and protect resources and habitats most vulnerable to longer-term oil impacts.
3. **Later** - Oil has stranded.
    - Window may be open for days to months, or longer; and
    - Responders use habitat-appropriate shoreline cleanup options to minimize environmental effects and enhance natural recovery (in some cases, oil may be left to degrade naturally because physical removal would cause a greater negative impact than leaving it in place).

Options for reducing spill impacts during each of these windows are addressed later, but, because information regarding Window 2 will be site-specific (and is addressed in area contingency plans), the emphasis here is on Windows 1 and 3. Figure 1 depicts the range of response possibilities for a generic, large marine oil spill (generalized response phases and windows illustrate the relative timing constraints of various response options).

Incident start (window of opportunity) →	. . . hours . . . (very early) →	. . . hours/days/weeks . . . (early) →	. . . months . . . (later)
PHASE / STRATEGY	STABILIZE/SECURE SOURCE	ON-WATER CONTAIN/ RECOVER/PROTECT	SHORELINE TREATMENT/CLEANUP

Figure 1. Types of response options within different windows of opportunity during a major oil spill (modified from Walker et al., 1993).

Incident-specific Feasibility Issues

After assessing the situation, defining goals, priorities, objectives, and identifying the possible response strategies, the next step is to consider the feasibility of field operations. Tables 1 and 2 summarize the issues (discussed in detail in the following section) to be considered in developing incident-specific, on-water and shoreline operations.

Table 1. Incident-specific **on-water** strategy issues.

Category	Issues
Nature and Amount of Oil	• Oil type spilled • Oil volume and area and shape of slick(s) and stranded oil • Variations in oil thickness and distribution • Emulsification
Proximity	• Source considerations • Water depths • Shoreline and resources at risk • Air and vessel traffic • Equipment staging and support locations • Special consideration areas
Timing	• Personnel and equipment availability • Logistics support for sustained operations • Time until impact • Weathering

Table 1. (cont.)

Category	Issues
Environment	• Weather (wind/rain, other precipitation) • Water depth • Wind and waves • Tides and currents • Visibility • Temperature • Ice and floating debris • Vulnerable species and habitats • Human use
Authorization	• Approval to burn and/or apply chemical countermeasures* • Approval to access restricted areas • Transport and disposal of recovered oil or waste • Permits

* Agents requiring approval can include dispersants, surface washing agents, surface collecting agents, bioremediation agents, burning agents, and miscellaneous oil spill control agents. In-situ burning also requires RRT approval or pre-approval.

Table 2. Incident-specific **shoreline** strategy issues.

Category	Issues
Safety	• Slip and fall hazards • Worker oil exposure hazards • Other hazards posed by the environment or location
Nature and Amount of Oil	• Oil type spilled • Stranded oil amount in terms of percent cover, thickness, width • Stranded oil distribution
Proximity	• Access from water and/or roads • Worker support services • Staging/deployment sites
Timing	• Timely strategy development • Rapid cleanup to prevent oil remobilization
Environment	• Waves • Tides • Currents • Weather (wind/rain, other precipitation) • Shoreline type • Water depth and sea bottom character

Table 2. (cont.)

Category	Issues
Environment	• Vulnerable and threatened/endangered species and habitats • Human use constraints • Cultural constraints
Authorization	• Approval to burn and/or apply chemical countermeasures* • Required consultations for protection species and cultural resources • Approval to access restricted areas • Transport and disposal of recovered oil or waste • Permits

* Agents requiring approval can include dispersants, surface washing agents, surface collecting agents, bioremediation agents, burning agents, and miscellaneous oil spill control agents. In-situ burning requires RRT approval or pre-approval.

On-Water Feasibility Issues

On-water response strategies must address a broad range of site-, spill-, and environment-specific issues, including:

- Safety risks;
- Environmental effects; and
- Timing, spatial, and environmental limits.

These must be carefully considered in establishing response option performance levels. Safety is always paramount. How other issues are prioritized can be different for each spill.

Nature and Amount of Oil

Oil Type

Identifying the type of oil spilled and being able to anticipate its changing physical and chemical character as it spreads and degrades will help responders:

- Conduct personnel safety assessments;
- Determine fire or explosion risks;
- Identify response option feasibility;
- Determine the resources at risk; and
- Determine windows of opportunity.

Oil Volume, Area, and Shape

Because on-water response equipment has predictable, limited areal coverage rates, a slick's volume, changing area, and shape as it is transported and spread by wind and currents will determine response option feasibility, effectiveness, and efficiency. Since mechanical recovery will remove only a fraction of the oil spilled:

- Spills on-water must be attacked early (a sudden release, even in a light surface current, can spread and be transported rapidly beyond any at-source containment; moderate- to large-volume spills on the order of 1,000 barrels or more can easily spread over 1–10 square miles [3–26 square kilometers] in a day or two); and
- Response methods should be combined wherever possible (large spills can quickly exceed the holding capacity of most containment barriers and skimming systems).

Variation in Oil Thickness and Distribution

Oil thickness can vary by orders of magnitude within different parts of a slick, thus the actual slick thickness and oil distribution of target areas are crucial for determining response method feasibility. Figure 2 illustrates the general relationships between on-water response techniques and slick thickness. Wind-rows, heavy oil patches, tarballs, etc., must be considered, as they influence oil encounter rates, chemical dosages, and ignition potential. Each method has different thickness thresholds for effective response.

Emulsification

Weathering often involves water-in-oil emulsification, which can impair response operations by:

- Increasing overall oil volume and recovered fluid storage requirements;
- Decreasing oil's buoyancy (increasing its tendency to submerge);
- Increasing the oil's viscosity (or pumpability) and stickiness (complicating recovery operations);
- Decreasing the oil's affinity for surface tension modifiers (reducing its dispersibility);
- Decreasing the oils' ignitability (burning is difficult or impossible once the water content reaches greater than 25%); and
- Decreasing available surface area for biodegradation (less biodegradable).

All of the above are important for understanding and estimating on-water response effectiveness, since some options may only be appropriate for a few hours under adverse conditions, or for several days during ideal conditions.

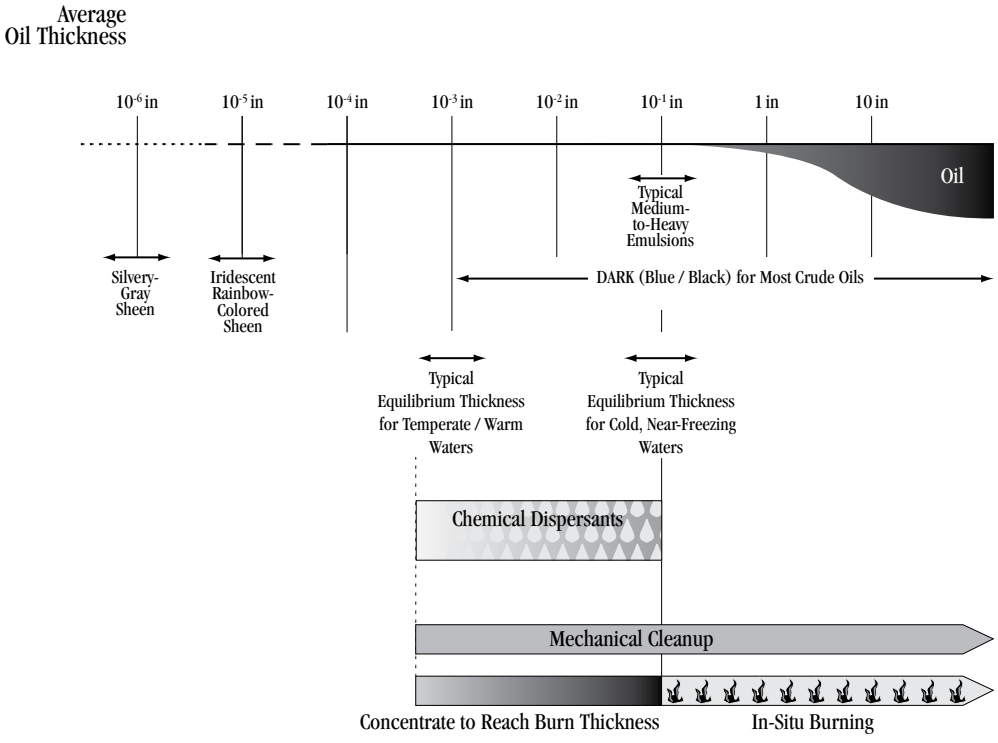

Figure 2. Oil thickness versus potential response options (modified from Allen and Dale, 1996).

Proximity

Source Considerations

Response operations must be conducted at safe distances from existing or potential spill sources, to reduce the risks of accidental ignition, exposure to harmful vapors, or changes in source characteristics that could endanger personnel or equipment.

Shoreline and Resources at Risk

Recovering or treating oil at sea can reduce the consequences to open-water and shoreline resources. Distance to shore is important because it will influence the type of vessels and equipment employed (size, draft, maneuverability, anchoring limitations) and the response countermeasures used. It is often more efficient and effective to recover or treat oil before it comes ashore.

Air and Vessel Traffic

On-water response and monitoring normally involve boats and/or aircraft, and activities of these vehicles must be carefully planned and controlled to prevent interference with other, ongoing (or planned) operations.

Equipment Staging and Support Locations

Response success will depend, in part, on the proximity of equipment and personnel staging locations to actual operations. Because response activities may interfere with each other (e.g., vessels transiting to and from staging areas) or with private or commercial activities, support operations will require careful planning.

Designated Special Consideration Areas

Designating certain areas as public, private, or government Special Consideration Areas may be necessary for conducting effective on-water operations. These areas may include national marine sanctuaries, national parks, archaeological sites, military operations areas, or may be pre-designated chemical dispersant operations or in-situ burning areas. Some Special Consideration Areas may have special activity or time requirements.

Timing

Personnel and Equipment Availability

The time required to bring resources to the scene will be a significant factor in establishing an effective response. Because response operations are critically influenced by oil spreading, transport, and weathering, realistic estimates of time to arrive on-scene must be established in response plans and re-evaluated as daily Incident Action Plans are developed.

Logistics Support for Sustained Operations

Effective, sustained response operations must be supported with:

- Trained, well-rested personnel for crew rotations (food, shelter);
- Spare parts and supplies (fuel, dispersants, personal protection equipment, boom, ignition systems, etc.) to keep equipment and personnel functioning;
- Secondary storage containers for recovered oil/water; and
- Sufficient, certified final disposal sites.

Time Until Shoreline Impact

Responders must determine realistic oil encounter and recovery rates to maximize the time available before oil impacts sensitive resources. If estimates show that on-water, mechanical response systems cannot handle a sufficient portion of a spill, the environmental impact trade-offs between containment and mechanical recovery, dispersant use, or in-situ burning must be carefully weighed against the impacts of that same oil reaching the shoreline. In some instances, it may be necessary to forego some on-water response in order to focus personnel and equipment resources on shoreline protection and cleanup.

Oil Weathering

During the first 24 to 48 hours of open water exposure, most oil spills become difficult to recover, burn, or chemically disperse, because:

- Evaporation accelerates as oil spreads and thins;
- Density and viscosity may increase;
- Tendency for emulsification can produce oily fluids of greater volume and viscosity than the original spill; and
- Slick thickness decreases quickly.

Environment

Water Depth

Shallow-water response requires careful use of response equipment, since:

- Vessel size and/or draft will limit speed, maneuverability, and operating areas;
- Vessel or boom anchors can disturb benthic communities;
- Shallow-water locations with strong currents create unique problems:
  - Booms with a draft greater than 1/4 the water depth will lose significant amounts of oil from entrainment.
  - Vessel squat (settling of the stern as speed increases) may limit operating areas or parameters.

Chemical dispersant use must not expose the biota to harmful concentrations of dispersed oil unnecessarily. There are usually minimum depth restrictions for their application offshore.

Water depth may be a consideration during in-situ burning deliberations because residues may sink, but heat transferred from a burning slick to the water is negligible and will not be a factor.

Wind and Waves

All weather will affect spill response activities. Rising wind and waves will:

- Increase oil spreading, transport, evaporation, and emulsification;
- Increase responder fatigue due to vessel and equipment handling difficulties; and
- Reduce all kinds of boom effectiveness.

While there are exceptions for certain types and conditions of oil, and specific types of equipment or dispersant, Figure 3 illustrates wind and wave influences on response operations feasibility over a broad range of average oil film thicknesses:

- **Mechanical Cleanup:** Effectiveness drops significantly because of entrainment and/or splash-over as short-period waves develop beyond 2–3 ft (0.6–0.9 m) in height. The ability to contain and recover oil decreases rapidly as the slick thickness becomes less than a thousandth of an inch (i.e., very low oil encounter rates). Waves and wind can also be limiting factors for the safe operation of vessels and aircraft.
- **Dispersants:** Effective dispersion requires a threshold amount of surface mixing energy (typically a few knots of wind and a light chop) to be effective. At higher wind and sea conditions, dispersant evaporation and wind-drift will limit chemical dispersion application effectiveness; and, there is a point (~25-kt winds, 10-ft [3 m] waves) where natural dispersion forces becomes greater, particularly for light oils. Because of droplet size versus slick thickness constraints and application dose-rate limitations, dispersants work best on slick thicknesses of a few thousandths to hundredths of an inch. Improved dispersants, higher dose rates, and multiple-pass techniques may extend the thickness limitation to 0.1 inch (0.25 cm) or more.
- **Burning:** Fire boom is affected by the same entrainment and splash-over problems as most conventional booms in 2–3 ft (0.6–0.9 m), short-period waves. Sustained burning is easiest during calm conditions and normally requires a minimum oil thickness of about 0.1 inch (0.25 cm); heavier and emulsified oils have to be thicker. It may be possible to contain and concentrate thinner slicks to minimum combustion thickness. It becomes very difficult to ignite oil on water when the winds approach 20 knots, but once ignited the burn can be sustained at much higher winds.

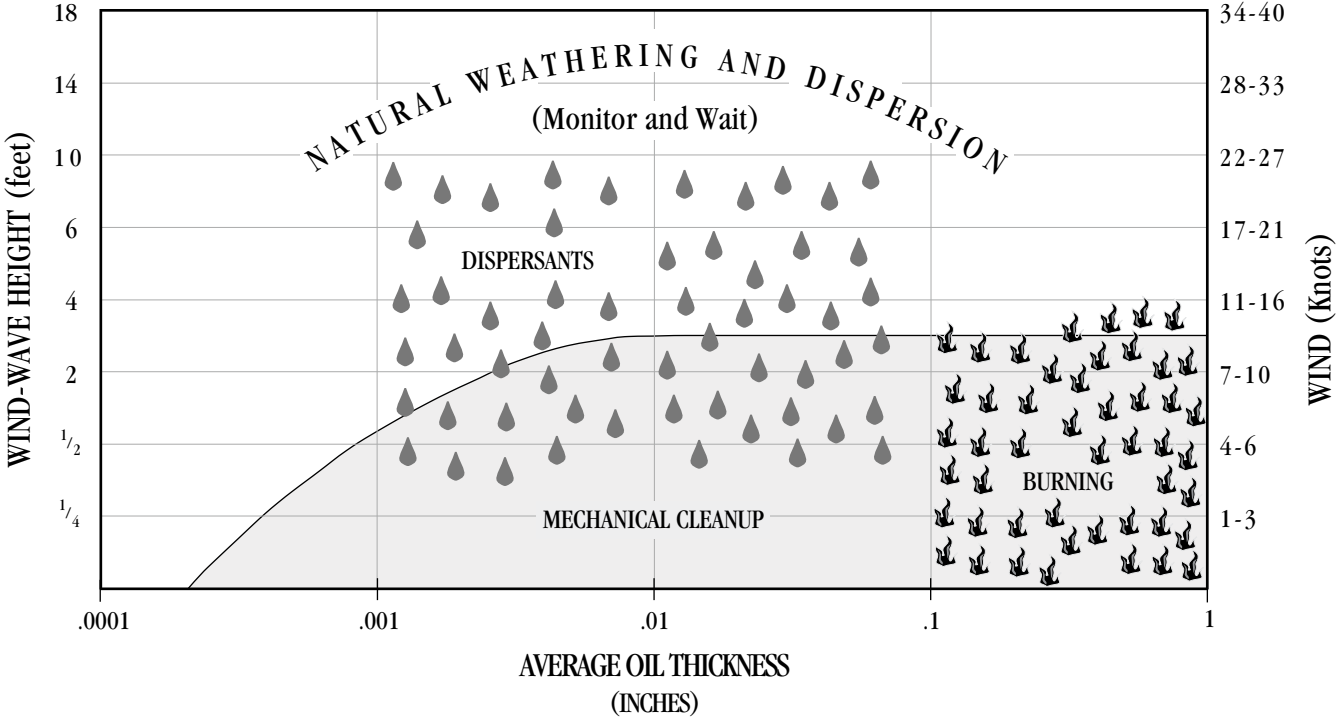

Figure 3. Primary spill response options under various wind/sea conditions and oil film thicknesses (modified from Allen, 1988).

Tides and Currents

Tides can:

- Change or reverse the direction and speed of water flow; and
- Change water depth.

Tides and currents can:

- Operate with wind to transport surface and subsurface oil over great distances.

Thus, tide and currents will dictate vessel size and power requirements; anchor size, type, and placement; towed boom drift distances; the time and location of possible sensitive resource impacts; and the amount of oil loss from entrainment (particularly with high-viscosity oils and oils of density near 1.0). Booming and skimming while drifting with the current will help minimize such losses.

Visibility

If response activities are conducted in low visibility, artificial light, or bright moonlight it will be difficult to find the heaviest oil concentrations or to monitor oil losses from booms and skimmers. Depending upon incident specifics, it may be feasible to conduct on-water operations in static or on-station modes during low visibility, allowing oil to come to recovery sites. Visibility is also important for dispersant application, for both the application and spotter aircraft.

Temperature

Low temperatures will generally increase oil viscosity (requiring viscous-oil recovery system use); inhibit spreading, evaporation, and emulsification; and may extend response windows of opportunity (but some oils may form stable emulsions in low temperatures). During extreme cold weather, ice may limit the spread of oil and improve the chances of recovery or burning. Extreme cold will also increase hypothermia potential, requiring responders to use special, cold-weather personal protection equipment, machinery, and procedures.

In high temperature and humidity situations, the above constraints will usually be reversed: oil will spread and evaporate faster, increasing fire and explosion potential for lighter oils, accelerating weathering processes, reducing response windows, and impacting equipment deployment times (equipment that works better on thicker oils that have retained their lighter ends must be deployed quickly). Extreme heat and humidity will also increase hyperthermia potential, requiring use of warm-weather personal protective equipment procedures and machinery.

Ice and Floating Debris

In some situations, ice or other floating debris may actually help contain oil and enhance in-situ burning, but heavy concentrations, particularly in strong currents, will clog, overload, or destroy most interception barriers. Debris will also tend to keep oil thick, dampen waves, and reduce dispersant effectiveness.

Frequent surveillance, and assigning resources to keep debris clear of recovery operations, will be necessary. If the debris is not too large, responders may be able to use barriers or screens with relatively narrow oil interception swaths.

Authorization

Approval to Burn and/or Apply Dispersants

In-situ burning or dispersant use requires government authorization (generally requested by the party responsible for the spill). Because safety, environmental impact, wildlife, and public concern issues are involved, most Regional Response Teams (RRTs) have established, as part of the regional response plan, zones and conditions under which use of in-situ burning and/or dipsersants can be authorized by the Federal On-Scene Coordinator (FOSC). In areas where use is "pre-approved," the FOSC can authorize use of in-situ burning or dispersants without further approvals; in areas where approval is "case-by-case," the FOSC must seek approval from the RRT. Specific conditions are usually applied regarding:

- Zone and boundary designations;
- Presence of sensitive on-water resources such as birds or marine mammals, especially threatened and endangered species;

- Distances from shore;
- Water depths;
- Weather; and
- Time (daylight, season).

Approval to Access Restricted Areas

Vessels and/or aircraft response operations may require special clearances or approvals, particularly near shore, where residential, commercial, industrial, recreational, or environmentally sensitive areas may be directly or indirectly impacted. Permission from government or owners/operators may be necessary before responders can enter or use these areas.

Transport and Disposal of Recovered Oil or Waste

Response planners must assess the time, cost, and effectiveness of storing, transporting, and disposing of recovered oil/oily wastes, including the effects that such operations will have on available resources (e.g., the length of time that response systems may be suspended due to lack of storage space). Disposal of recovered oil and oily wastes must comply with government regulations. Planners must also address:

- Temporary storage (onshore, offshore) of oil and oily debris, or sorbent materials;
- Decanting and discharging free water from recovered fluids;
- Transfer of waste from vessels/barges to onshore facilities;
- Handling waste from offshore equipment/vessel cleaning operations;
- Disposing of waste, burn residue, and debris at approved sites; and
- Product sampling and analyzing.

Shoreline Feasibility Issues

Shoreline response strategies may be constrained by safety, physical, or environmental considerations.

Safety

The dangers or risks inherent in land-based operations involving mechanized equipment are similar to those of on-water activities. Though less critical on land, weather-related hazards from high winds, waves, currents, and tides still exist near the shoreline.

Stranded oil, or nearshore oil, has usually weathered, and the threat of harmful exposures or accidental ignition is lower than at, or near, its source. However, some oils may still contain enough light ends to make exposure, inhalation, or ingestion risky (except for asphalt-type oils).

Nature and Amount of Oil

Understanding how a particular spill has weathered will help responders select appropriate treatment or cleanup options. Such information can be gathered by shoreline assessment surveys; these involve systematically collecting data to describe (using standard terms) the location, amount, distribution, and character of stranded or nearshore oil.

Proximity

Responders must consider shoreline proximity issues so that inshore, on-water operations can be safely conducted. Considerations may include distance(s) to:

- Safe or sheltered anchorage;
- Support services (e.g., medical, food, lodging, maintenance and repair, and communications);
- Suitable staging or deployment sites; and
- Shoal waters, uncharted, underwater obstacles, etc.

Timing

Shoreline assessments must be conducted as soon as possible so that planners can incorporate the information into response strategies and provide sufficient resources to remove the oil and prevent it from refloating and impacting other areas.

Environment

The operating environment for shoreline protection and cleanup involves a number of issues, including: waves and breakers, tides, currents, water depths, weather, shoreline features, ecological constraints, human use or cultural resource constraints, and public or government requirements or perceptions.

Waves

Small boats operating near shore, or responders working near the water's edge, are directly exposed to hazards from nearshore waves. Although these can usually be easily seen and activities adjusted to account for them, unexpected or unpredictable conditions can occur, since:

- Vessel wakes can travel several miles, and produce unexpected, steep, breaking waves 3–4 ft (0.9 or 1.2 m) high;
- Wave heights can vary unexpectedly (and rare, but dangerous, "rogue" waves can occur on open ocean coasts); and
- Dangerous wave backwash and rip currents are common along open ocean coasts.

Most shallow- or calm-water booms are ineffective in waves over 2 ft, because they cannot follow short, choppy waves. Although specifically designed for use at the water's edge, shoreline or intertidal booms can be easily rolled or twisted by wave action.

Tides

Though tides and currents are predictable, rapid changes in water level can isolate and strand unwary personnel, particularly in areas with a high tidal range, or on wide, flat intertidal areas. Tidal changes from storm surges or wind setups are not as readily predictable, but must also be considered.

Currents

Nearshore currents may be strong (particularly tidal inlet currents, longshore currents, or rip currents), and booms must be regularly redeployed or reconfigured to account for changing water flow.

Weather

Coastal weather can change rapidly and responders must consider the risks from:

- High wind – violent winds (wind shear/microbursts);
- Remote access – isolation of responders;
- Low visibility – fog, rain, snow, smoke, darkness, or extreme light intensity (e.g., glare);
- Ice formation – rafting, damming, or breakup, sea/river ice floes vessel, or equipment icing;
- Lightning – consider evacuation protocols when electrical storms are forecast or observed;
- Intense precipitation – flooding, ground destabilization (mudslides/sinkholes); and
- Extreme temperature/humidity – hypothermia/hyperthermia.

Shoreline Condition

Not all response methods are appropriate for every shoreline type; some may be impractical, unfeasible, environmentally intrusive, or damaging. Shoreline conditions to be evaluated, so responders can select proper response methods, should include:

- Rock falls or slides from backshore cliffs;
- Slippery rock surfaces;
- Presence of ice;
- Limited bearing capacity on mud flats, sand flats, beaches, backshore areas;
- Beach or backshore width and accessibility; and
- Surface mat stability in floating marshes (bogs).

Water Depths and Sea Bottom Character

Nearshore operational safety depends, in part, on responders' knowledge of bottom configuration and navigation conditions (e.g., bottom conditions will dictate which anchors or mooring systems will work; generally, rock bottoms provide poor anchorage). Keys to success include local knowledge, and the scale, accuracy, and availability of:

- Nautical charts; and
- Sailing directions and Notices to Mariners.

Environmental (Ecological) Constraints

Response strategies must allow responders to meet defined response objectives without causing more damage than the oil itself. If, after initially removing gross oil amounts, the level of intrusion necessary to remove any residual oil may cause unacceptable changes, damage, or become inefficient, response activities should be modified.

Certain animals, plants, or insects may be hazardous to shore-zone responders, and response managers must make full use of local knowledge to help reduce such risks (during the Exxon Valdez response, armed guards and training of field personnel were used to protect responders from Kodiak brown bears).

Human Use Constraints

Day-to-day human activities can affect responder safety afloat and/or ashore:

- Small boats, commercial traffic, ocean-going vessels, and/or ferries may transit areas where response activities are planned or underway–boat wakes can interfere with nearshore response operations;
- Vehicle traffic on piers, wharves, docks, or backshore roads may be dangerous; and
- Backshore residential, commercial, industrial, or recreational activities may conflict with response operations.

Cultural Constraints

Historically and culturally significant sites, or resources, are found on all coasts. Even if these sites are not directly affected by oil, shoreline activities may result in contact with these resources.

If such sites are present within response areas, special permission will normally be required from cognizant tribal, government, cultural, historic, or archaeological organizations prior to commencing clean-up activities.

Authorization

In addition to shoreline access, which may require permission from outside the response organization, government organizations:

- May restrict use of non-mechanical countermeasures; and
- Require specific authorization and permits to transport and dispose of recovered oily wastes, including temporary storage.

Process for Developing Incident-Specific Strategies

Spill response management follows a general sequence of steps for each spill, spill phase, and response location:

1. Gather information and assess the situation.
2. Define response goals and priorities.
3. Define response objective(s).
4. Develop strategies to meet the objectives, based on windows of opportunity.
5. Evaluate the feasibility of the options and strategies in view of the environmental conditions and spill specifics.
6. Select response options and tactical arrangements to implement identified strategies (begin process to obtain necessary approvals, permissions, permits).
7. Prepare an Incident Action Plan for carrying out the identified strategies.
8. Implement field response operations plans for each strategy.

While certain objectives, strategies, and tactics can be identified before an incident, and will usually be included in both owner/operator response plans and area contingency plans, responders must develop incident-specific response strategies (step 4, above) at the time of the incident. Steps 4, 5, and 6 are related to the incident response objectives, and are subject to a variety of incident-specific conditions, such as those discussed in detail in the remainder of this section. The remaining steps will be highly incident-specific so that discussing them further in this manual is not possible.

Integration of On-water Response Options

If a response objective is to minimize or prevent shoreline impact, using multiple, integrated on-water countermeasures offers the best chance of success. Thus, if "very early" window of opportunity options are to be used, decision-making, strategic plan development and approvals, and implementation must be rapid. Each response tool has advantages, disadvantages, and limitations in its effectiveness. Decision-makers must weigh various trade-offs when considering and

comparing response options. Since there is not one perfect response option, the best solution is to use all the "tools in the toolbox" in combined (integrated) operations to achieve response objectives. In general, these tools include:

- Monitor and wait. No active response to remove oil;
- Physical containment and mechanical recovery. Removes oil from the water with few environmental impacts but involves operational limitations associated with weather, visibility, physics, logistics, etc.;
- Dispersant application. Protects waterfowl and shoreline habitats but increases oil in the water column and exposure of water-column and benthic organisms to oil;
- In-situ burning. Protects sensitive shoreline habitats by removing floating, burnable oil; but heavy, black smoke is unsightly, alarming, and can be a respiratory hazard for humans and animals. Removal of burn residue may be technologically difficult, and unrecovered burn residue may further damage the environment; and
- Allow the oil to strand on shore. Shoreline cleanup will not disrupt water-column biota but allowing oil to reach shore means that intertidal and nearshore subtidal habitats and biological communities will be impacted.

Temporal Considerations

Mechanical recovery, dispersant application, and in-situ burning operations can be used singularly, or in combination, to improve efficiency and effectiveness.

- Mechanical recovery: oil that escapes containment or recovery will still be available for subsequent mechanical removal, treatment with dispersants, or for burning;
- Dispersants: some of the dispersant-treated slick may actually be missed and be available for additional dispersant operations, burning, or mechanical containment and recovery (except oleophilic skimmers for a few hours). Also, containing and burning a partially treated slick should remain viable, since dispersant application may decrease the slick's tendency to emulsify and prolong or reopen the window of opportunity for burning;

- Burning: most (>90%) of the oil burned will be converted to carbon dioxide, water vapor, and soot. Any oil that escapes the fire boom will be available downstream for re-collection and burning, mechanical recovery, or dispersant treatment; and
- The residues from a successful burn or partially-burned Categories III and IV oils, on the other hand, are not suitable for chemical dispersion. However, residues can be physically removed using viscous-oil recovery systems, or nets and hand tools. If partially burned oil/residue sinks, then the environmental consequences of leaving the submerged oil must be compared to the feasibility and consequences of removing the submerged material.

Spatial Considerations

Integrating response options also includes spatial considerations. For safety reasons, combined, simultaneous operations should be conducted only in designated safe operating zones that take into account spill and site specifics:

- Response vessels must always be far enough apart to preclude near-misses, collisions, or other disruptions of operations;
- Aircraft operations must be coordinated through a single air-traffic control system with specific directives for: allowable altitudes, air space, air and surface radio frequencies, emergency procedures, etc.;
- Mechanical cleanup and in-situ burning operations should be positioned in the thickest layers of oil, consistent with safety and environmental constraints;
- Burning should be positioned and conducted to: 1) avoid ignition of source; 2) avoid endangering personnel, facilities, vessels, or equipment downstream/downwind; 3) prevent accidental ignition of nearby contained or uncontained slicks or vapors; and
- Dispersants should be used on slicks that are sufficiently downstream/downwind from other operations that wind or current will not carry dispersant into those operating areas. Safe operating distances will be spill-specific.

Shoreline Strategies

Shoreline response strategies differ from on-water response strategies because:

- Stranded oil generally remains in place or is relatively slow-moving; and
- Land-based operations usually are less weather-dependent than water-based activities, and there are different safety and feasibility factors to consider.

Since shoreline response can be a long-term operation (days-weeks-months), integrating and combining multiple shoreline protection and cleanup options into strategies that are implemented simultaneously is common practice (nearshore containment and recovery often take place alongside various types of shoreline cleanup).

The following discussion includes all options operated from shore.

Shoreline Protection

The basic shoreline protection objective is to:

- Prevent or minimize contact between oil and the shore zone (or a resource at risk in the zone).

This can be done by combining activities, techniques, and equipment to:

- Remove shoreline debris before the oil is washed ashore;
- Contain and recover floating oil prior to shoreline impact;
- Deflect oil away from shore;
- Trap or contain and collect oil at the shoreline;
- Prevent stranded oil from refloating and affecting adjacent areas; and
- Prevent oil being washed over a beach into a lagoon or backshore area.

Shoreline Treatment and Cleanup

For an oiled shoreline, the main treatment objective is often to restore the oiled shore zone to a pre-spill "clean" condition. But defining a specific level of "clean" will be different for each spill (or even different for different phases of a single response) and, although promoting recovery usually includes removing some portion of the oil and allowing the rest of the oil or residue to degrade naturally, the best course of action may be to let all the oil degrade naturally. Final levels of allowable oil concentrations can, and should, be determined by consensus (considering overall environmental consequences) during contingency planning and sensitivity mapping before any spill. This process should balance conflicting environmental and socioeconomic concerns.

Reducing overall environmental consequences in an effective and efficient manner usually requires a combination of techniques, including:

- Natural recovery;
- Physical washing/flushing;
- Physical removal;
- Physical in-situ treatment (including burning); and
- Chemical or biological treatment.

Natural Recovery

Objective:	No attempt to remove any stranded oil either to minimize impacts to the environment or because there is no effective method for cleanup. Oil is left in place to degrade naturally.
Description:	No action is taken, although monitoring of contaminated areas may be required.
Applicable Habitat Types:	All habitat types.
When to Use:	When natural removal rates are fast (e.g., gasoline evaporation, high-energy coastlines), when the degree of oiling is light, or when cleanup actions will do more harm than natural recovery.
Biological Constraints:	This method may be inappropriate for areas used by high numbers of people, mobile animals (birds, marine mammals) or endangered species.
Environmental Effects:	Same as from the oil alone.
Waste Generation:	None.

Booming

Objective:	To prevent oil from contacting resources at risk, and to facilitate oil removal.
Description:	A boom specifically designed for pollution response is a floating, physical barrier, placed on the water to contain, divert, deflect, or exclude oil. Containment is deploying a boom to contain and concentrate the oil until it can be removed. Deflection is moving oil away from sensitive areas. Diversion is moving oil toward recovery sites that have slower flow, better access, etc. Exclusion is placing boom to prevent oil from reaching sensitive areas. Booms must be properly deployed, maintained) including removing accumulated debris), and re-adjusted to changing water flow directions, water levels, and wave conditions. Proper deployment involves use of mooring systems (e.g., anchors, land lines) and skilled teams. Tidal-seal boom is a special type of boom designed to be deployed in the intertidal zone.
Applicable Habitat Types:	Can be used on all water environments (weather permitting). Booms begin to fail by entrainment when the effective current or towing speed exceeds 0.7 knots perpendicular to the boom. Waves, wind, debris, and ice contribute to boom failure.
When to Use:	Most responses to spills on water involve deploying boom to help facilitate the removal of floating oil and prevent oil from contacting sensitive resources. Containment booming of gasoline spills is usually not attempted, because of fire, explosion, and inhalation hazards. However, when public health is at risk, gasoline can be boomed if foam is applied and extreme safety procedures are used.

Booming (cont.)

Biological Constraints:	Placing and maintaining boom and anchoring points should not cause excessive physical disruption to the environment, and both must be maintained so they do not fail or tangle and cause more damage. Vehicle and foot traffic to and from boom sites should not disturb wildlife unreasonably, and booms in very shallow water should be monitored so they do not trap wildlife (such as migrating turtles returning to sea or fish coming in at high tide).
Environmental Effects:	Minimal, if disturbance during deployment and maintenance is controlled.
Waste Generation:	Cleaning booms will generate contaminated wastewater that must be collected, treated, and disposed of appropriately. Discarded booms will need to be disposed of according to appropriate waste disposal regulations.

Skimming

Objective:	To recover floating oil from the water surface using mechanized equipment. This includes specifically designed pollution equipment called skimmers, and other mechanical equipment such as draglines and dredges.
Description:	There are numerous types of skimming devices, described in the annually published World Catalog of Oil Spill Response Products (SL Ross 2008): brush, disc, drum, paddle, belt, rope mop, sorbent belt, submersion plan, suction, and weir. They are placed at the oil/water interface to recover, or skim, oil from the water's surface and may be operated independently from shore, be mounted on vessels, or be completely self-propelled. Because large amounts of water are often simultaneously collected (incidental to skimmer operation) and treated, efficient operations require that floating oil be concentrated at the skimmer head, usually using booms. Adequate storage of recovered oil/water mixtures must be available, as must suitable transfer capability. Skimmers are often placed where oil naturally accumulates in pockets, pools, or eddies.
Applicable Habitat Types:	Can be used on all water environments (weather and visibility permitting). Waves, currents, debris, seaweed, kelp, ice, and viscous oils will reduce skimmer efficiency.
When to Use:	When sufficient amounts of floating oil can be accessed. Skimming spilled gasoline is usually not feasible because of fire, explosion, and inhalation hazards to responders. However, when public health is at risk, gasoline can be skimmed if foam is applied and extreme safety procedures used.

Skimming (cont.)

Biological Constraints:	Vehicle and foot traffic to and from skimming sites should not disturb wildlife unreasonably.
Environmental Effects:	Minimal if surface disturbance by cleanup work force traffic is controlled.
Waste Generation:	Free-floating oil can be recycled. Emulsions formed during the process must be treated (broken) before recycling. Oil-contaminated waste from the treatment phase should be treated as wastewater. Co-collected water must be properly treated prior to discharge.

Barriers/Berms

Objective:	To prevent entry of oil into a sensitive area or to divert oil to a collection area.
Description:	A physical barrier (other than a boom) is placed across an area to prevent oil from passing. Barriers can consist of earthen berms, trenching, or filter fences. When it is necessary for water to pass because of water volume, underflow or overflow dams are used.
Applicable Habitat Types:	At the mouths of creeks or streams to prevent oil from entering, or to prevent oil in the creek from being released into offshore waters. Also, on beaches where a berm can be built above the high-tide line to prevent oil from overwashing the beach and entering a sensitive back-beach habitat (e.g., lagoon).
When to Use:	When the oil threatens sensitive habitats and other barrier options are not feasible.
Biological Constraints:	Responders must minimize disturbance to bird nesting areas, beaver dams, or other sensitive areas. Placement of dams and filter fences could cause excessive physical disruptions, particularly in wetlands.
Environmental Effects:	May disrupt or contaminate sediments and adjacent vegetation. The natural beach (or shore) profile should be restored (may take weeks to months on gravel beaches). Trenching may enhance oil penetration and quantity of contaminated sediments. May require Army Corps of Engineers permit.
Waste Generation:	Sediment barriers will become contaminated on the oil side and filter fence materials will have to be disposed of as oily wastes.

Physical Herding

Objective:	To free any oil trapped in debris or vegetation on water; to direct floating oil towards containment and recovery devices; or to divert oil from sensitive areas.
Description:	Plunging water jets, water or air hoses, and propeller wash can be used to dislodge trapped oil and divert or herd it to containment and recovery areas. May emulsify the oil. Mostly conducted from small boats, although larger boats such as tugs can be used to generate stronger currents or influence larger areas (such as oil trapped deep under piers).
Applicable Habitat Types:	In nearshore areas where there are little or no currents, and in and around man-made structures such as wharves and piers.
When to Use:	In low-current or stagnant water bodies, to herd oil toward recovery devices. In high-current situations to divert floating oil away from sensitive areas.
Biological Constraints:	When used nearshore and in shallow water, must be careful not to disrupt bottom sediments or submerged aquatic vegetation.
Environmental Effects:	May generate high levels of suspended sediments and mix them with the oil, resulting in deposition of contaminated sediments in benthic habitats.
Waste Generation:	None.

Manual Oil Removal/Cleaning

Objective:	To remove oil with hand tools and manual labor.
Description:	Removal of surface oil using hands, rakes, shovels, buckets, scrapers, sorbents, pitchforks, etc., and placing in containers. No mechanized equipment is used except for transport of collected oil and debris. Includes underwater recovery of submerged oil by divers, for example, with hand tools.
Applicable Habitat Types:	Can be used on all habitat types.
When to Use:	Light to moderate oiling conditions for stranded oil, or heavy oils on water or submerged on the bottom that have formed semi-solid or solid masses and that can be picked up manually.
Biological Constraints:	Foot traffic over sensitive areas (marshes, tidal pools, etc.) should be restricted or prevented. There may be periods when shoreline access should be avoided, such as during bird nesting.
Environmental Effects:	Minimal, if surface disturbance by responders and waste generation is controlled.
Waste Generation:	May generate significant quantities of oil mixed with sediment and debris that must be properly disposed of or treated. Decontamination of hand tools may produce oily wastewater that must be treated properly. Worker personal protective gear is usually disposed of daily or decontaminated and the resulting oily wastewater treated properly.

Mechanical Oil Removal

Objective:	To remove oil from shorelines, and bottom sediments using mechanical equipment.
Description:	Oil and oiled sediments are collected and removed using mechanical equipment not specifically designed for pollution response, such as backhoes, graders, bulldozers, dredges, draglines, etc. Requires systems for temporary storage, transportation, and final treatment and disposal of collected material.
Applicable Habitat Types:	On land, possible wherever surface sediments are both amenable to, and accessible by, heavy equipment. For submerged oil, used in sheltered areas where oil accumulates. On water, used on viscous or solid contained oil.
When to Use:	When large amounts of oiled materials must be removed. Care should be taken to remove sediments only to the depth of oil penetration, which can be difficult with heavy equipment. Should be used carefully where excessive sediment removal may cause erosion of the beach or shore. Mechanical removal of buried oil consists of removing both clean overburden and oiled sediments (it is seldom feasible to remove the clean layer of sediments for later replacement). If large amounts of sediment are removed, it may be necessary to artificially re-nourish the beach. Care is also needed to minimize further oil penetration from uncontrolled vehicle traffic.
Biological Constraints:	Heavy equipment use may be restricted in sensitive habitats (e.g., marshes, soft substrates) or areas used by protected species. Special permission will be needed to use heavy equipment in areas with known cultural resources. Dredging in seagrass beds or coral reef habitats may be prohibited. Access and work areas may be restricted to prevent physical disturbance to adjacent, unoiled areas.

Mechanical Oil Removal (cont.)

Environmental Effects:	The equipment is heavy, with many support personnel required. May be detrimental if excessive sediments are removed without replacement. All organisms in the sediments will be affected, although the need to remove the oil may make this response method the best overall alternative. Resuspension of exposed oil and fine-grained, oily sediments can affect adjacent bodies of water.
Waste Generation:	Can generate significant quantities of contaminated sediment and debris that must be treated or landfilled. The amount of waste generated by this cleanup option should be given careful consideration by response planners when reviewing potential environmental impacts of the oily wastes, debris, and residues.

Sorbents

Objective:	To remove surface oil by using oleophilic (oil-attracting) material placed in water or at the waterline.
Description:	Organic, inorganic, and synthetic materials that remove oil through absorption (uptake into the sorbent material, like a sponge) or through adsorption (coating of the sorbent's surface). Sorbents are placed on the floating oil or water surface, allowing them to sorb oil, or are used to wipe or dab stranded oil. Forms include sausage boom, pads, rolls, sweeps, snares, and granules or particles that are loose or in pillows or socks. Efficacy depends on the capacity of the particular sorbent, wave or tidal energy available for lifting the oil off the substrate, and oil type and stickiness. All sorbent material must be recovered. Loose particulate sorbents must be contained in a mesh or other material.
Applicable Habitat Types:	Can be used on any habitat or environment type.
When to Use:	When oil is free-floating close to shore, or stranded on shore; the oil must be able to be released from the substrate and sorbed by the sorbent. Sorbents can be used as a secondary treatment method after gross oil removal in sensitive areas where access is restricted. Selection of sorbent varies by oil type: heavy oils only coat surfaces, requiring use of sorbents with high surface areas to be effective; lighter oils can penetrate sorbent material. Loose sorbent may be applied on vegetated areas where oil poses wildlife contact hazards or generates sheens. Products that sink, either initially or over time, should not be used in areas where they could be released to water.

Sorbents (cont.)

Biological Constraints:	Access for deploying and retrieving sorbents should not 1) adversely affect wildlife; 2) be through soft or sensitive habitats. Sorbents should not be used in a fashion that would endanger or trap wildlife. Sorbents left in place too long can break apart and present an ingestion hazard to wildlife or smother animals and plants.
Environmental Effects:	Physical disturbance of habitat during deployment and retrieval. Improperly deployed or tended sorbent material can crush or smother sensitive organisms.
Waste Generation:	In most cases, sorbents must eventually be collected for proper disposal so care should be taken to select and use sorbents properly, and prevent overuse and generation of large amounts of lightly oiled sorbents. Because large amounts of waste may be generated, recycling should be emphasized over disposal.

Vacuum

Objective:	To remove oil pooled on a shoreline substrate or subtidal sediments.
Description:	A vacuum unit is attached via a flexible hose to a suction head that recovers free oil. The equipment can range from small, portable units that fill individual 55-gallon drums to large supersuckers that are truck- or vessel-mounted and can generate enough suction to lift large rocks. Removal rates from substrates can be extremely slow.
Applicable Habitat Types:	Any accessible habitat type. May be mounted on vessels for water-based operations, on trucks driven to the recovery area, or hand-carried to remote sites.
When to Use:	When oil is stranded on the substrate, pooled against a shoreline, concentrated in trenches, or trapped in vegetation. Usually requires shoreline access points.
Biological Constraints:	Special restrictions should be established for areas where foot traffic and equipment operation may be damaging, such as soft substrates. Operations in vegetated areas must be very closely monitored, and a site-specific list of procedures and restrictions developed to prevent damage to vegetation.
Environmental Effects:	Minimal, if foot and vehicular traffic are controlled and minimal substrate is damaged or removed.
Waste Generation:	Collected oil and/or oil/water mix will need to be stored temporarily before recycling or disposal. Oil may be recyclable; if not, it will require disposal in accordance with local regulations. Large amounts of water are often recovered, requiring separation and treatment.

Debris Removal

Objective:	To remove debris in the path of a spill before oiling, and to remove contaminated debris from the shoreline and water surface.
Description:	Manual or mechanical removal of debris (driftwood, seaweed, trash, wreckage) from the shore or water surface. Can include cutting and removal of oiled logs.
Applicable Habitat Types:	Can be used on any habitat or environment type where access is safe.
When to Use:	When debris is heavily contaminated and provides a potential source of secondary oil release; an aesthetic problem; a source of contamination for other resources in the area is likely to clog skimmers; or likely to cause safety problems for responders. Used in areas of debris accumulation on beaches before oiling to minimize the amount of oiled debris to be handled.
Biological Constraints:	Foot traffic over sensitive areas (wetlands, spawning grounds) must be restricted. May be periods when entry should be denied (spawning periods, influx of large numbers of migratory waterbirds). Debris may also be a habitat and important source of prey, there should no wholesale removal of unoiled debris..
Environmental Effects:	Physical disruption of substrate, especially when mechanized equipment must be deployed to recover a large quantity of debris. Loss of habitat and prey, such as wrack removal, can affect the food supply for shorebirds.

Debris Removal (cont.)

Waste Generation: Will generate contaminated debris (volume depends on what, and how much, is collected, e.g. logs, brush). Unless there is an approved hazardous waste incinerator that will take oily debris, burning will seldom be allowed, especially on-site burning. However, this option should still be explored, especially for remote locations, with the appropriate state or Federal agencies that must give approvals for burning.

The advantage of pre-spill debris collections is that waste disposal requirements will likely be less restrictive than if the debris is oiled. Once oiled, the debris is likely to be handled as a hazardous waste.

Sediment Reworking/Tilling

Objective:	To break up oily sediments and surface oil deposits, increasing their surface area, and mixing deeper subsurface oil layers, thus enhancing the rate of degradation through aeration.
Description:	The oiled sediments are roto-tilled, disked, or otherwise mixed using mechanical equipment or manual tools. Along beaches, oiled sediments may also be pushed to the water's edge to enhance natural cleanup by wave activity (surf washing). On gravel beaches, the process may be aided with high-volume flushing.
Applicable Habitat Types:	On any sedimentary substrate that can support mechanical equipment or foot traffic and hand tilling.
When to Use:	On sand to gravel beaches with subsurface oil, where sediment removal is not feasible (due to erosion or disposal problems). On sand beaches where the sediment is stained or lightly oiled. Appropriate for sites where the oil is stranded above the normal high waterline.
Biological Constraints:	Avoid use on shores near sensitive wildlife habitats, such as fish-spawning areas or bird-nesting or concentration areas because of the potential for release of oil and oiled sediments into adjacent bodies of water. Should not be used in shellfish beds or vegetated habitats.
Environmental Effects:	Mixing of oil into sediments could further expose organisms that live below the original layer of oil. Repeated reworking could delay re-establishing of these organisms. Refloated oil from treated sites could contaminate adjacent waterbodies and shorelines. Resuspension of exposed oil and fine-grained, oily sediments can affect adjacent waterbodies.
Waste Generation:	None.

Vegetation Cutting/Removal

Objective:	To remove portions of oiled vegetation or to access oil trapped in vegetation to prevent oiling of wildlife or secondary oil releases.
Description:	Oiled vegetation is cut with weed trimmers, blades, etc., and picked or raked up and bagged for disposal.
Applicable Habitat Types:	Habitats composed of vegetation, such as salt marsh, sea grass beds, and kelp beds, which contain emergent, herbaceous vegetation or floating, aquatic vegetation.
When to Use:	When the risk of oiled vegetation contaminating wildlife is greater than the value of the vegetation that is to be cut, and there is no less-destructive method that removes or reduces the risk to acceptable levels.
Biological Constraints:	Operations must be strictly monitored to minimize the degree of root destruction and mixing of oil deeper into the sediments. Access in bird-nesting areas should be restricted during nesting seasons. Cutting only the oiled portions of the plants and leaving roots and as much of the stem as possible minimizes impacts to plants.
Environmental Effects:	Vegetation removal will destroy habitat for many animals. Cut areas will have reduced plant growth and, in some instances, plants may be killed. Cutting at the base of the plant stem may allow oil to penetrate the substrate, causing sub-surface contamination. Along exposed sections of shoreline, the vegetation may not recover, resulting in erosion and habitat loss. Trampled areas will recover much more slowly.
Waste Generation:	Cut portions of oiled plants must be collected and disposed.

Flooding

Objective:	To wash oil stranded on land to the water's edge for collection.
Description:	A perforated header pipe or hose is placed above the oiled shore or bank. Ambient-temperature water is pumped through the header pipe at low pressure and flows downslope to the water where any oil released is trapped by booms and recovered by skimmers or other suitable equipment. On porous sediments, water flows through the substrate, pushing loose oil ahead of it. On saturated, fine-grained sediments, the technique becomes more of a surface flushing.
Applicable Habitat Types:	All shoreline types where the equipment can be effectively deployed. Not effective in steep intertidal areas.
When to Use:	In heavily oiled areas when the oil is still fluid and adheres loosely to the substrate, and where oil has penetrated into gravel sediments. This method is frequently used with other washing techniques (low- or high-pressure, cold- to hot-water flushing).
Biological Constraints:	May need to restrict use so that the oil/water effluent does not drain across sensitive intertidal habitats. Not appropriate for muddy substrates.
Environmental Effects:	Habitat may be physically disturbed by foot traffic during operations and smothered by sediments washed down the slope. Flooding may cause sediment loss and erosion of the shoreline and shallow rooted vegetation. Oiled sediment may be transported to nearshore areas, contaminating them and burying benthic organisms.
Waste Generation:	Depends on the effectiveness of the collection method.

Low-pressure, Ambient-Water Flushing

Objective:	To remove fluid oil that has adhered to the substrate or man-made structures, pooled on the surface, or become trapped in vegetation.
Description:	Ambient-temperature water is sprayed at low pressures (<10 psi), usually from hand-held hoses, to lift oil from the substrate and float it to the water's edge for recovery by skimmers, vacuum, or sorbents. Usually used with a flooding system to prevent released oil from re-adhering to the substrate downstream of the treatment area.
Applicable Habitat Types:	On substrates, riprap, and solid, man-made structures, where the oil is still fluid. In wetlands and along vegetated banks where oil is trapped in vegetation.
When to Use:	Where fluid oil is stranded onshore or floating in shallow intertidal areas.
Biological Constraints:	May need to restrict use so that the oil/water effluent does not drain across sensitive intertidal habitats, and so that mobilized sediments do not affect rich subtidal communities. Use from boats will reduce the need for foot traffic in soft substrates and vegetation. Flushed oil must be recovered to prevent further oiling of adjacent areas.
Environmental Effects:	If containment methods are not sufficient, oil and oiled sediments may be flushed into adjacent areas. Flooding may cause sediment loss and erosion of the shoreline and shallow rooted vegetation. Some trampling of substrate and attached biota will occur.
Waste Generation:	Depends on the effectiveness of the collection method.

High-pressure, Ambient-Water Flushing

Objective:	To remove oil that has adhered to hard substrates or man-made structures.
Description:	Similar to low-pressure flushing, except that water pressure is 100–1,000 psi (720–7,200 kpa). High-pressure spray will more effectively remove sticky or viscous oils. If low water volumes are used, sorbents are placed directly below the treatment area to recover oil.
Applicable Habitat Types:	On bedrock, man-made structures, and gravel substrates.
When to Use:	When low-pressure flushing is not effective at removing adhered oil, which must be removed to prevent continued oil release or for aesthetic reasons. When a directed water jet can remove oil from hard-to-reach sites.
Biological Constraints:	May need to restrict flushing so that the oil does not drain across sensitive habitats. Flushed oil must be recovered to prevent further oiling of adjacent areas. Should not be used directly on attached algae nor rich, intertidal areas.
Environmental Effects:	All attached animals and plants in the direct spray zone will be removed, even when used properly. May drive oil deeper into the substrate or erode fine sediments from shorelines if water jet is improperly applied. If containment methods are not sufficient, oil and oiled sediments may be flushed into adjacent areas. Some trampling of substrate and attached biota will occur.
Waste Generation:	Depends on the effectiveness of the collection method.

Low-pressure, Hot-Water Flushing

Objective:	To remove non-liquid/non-fluid oil that has adhered to the substrate or man-made structures, or pooled on the surface.
Description:	Hot water (90°F [32°C] up to 171°F [77°C]) is sprayed with hoses at low pressures (<10 psi [<72 kpa]) to liquefy and lift oil from the substrate and float it to the water's edge for recovery by skimmers, vacuums, or sorbents. Used with flooding to prevent released oil from re-adhering to the substrate.
Applicable Habitat Types:	On bedrock, sand to gravel substrates, and man-made structures.
When to Use:	Where heavy, but relatively fresh, oil is stranded onshore. The oil must be heated above its pour point so it will flow. Less effective on sticky oils.
Biological Constraints:	Avoid vegetated areas or rich intertidal communities so that the hot oil/water effluent does not contact sensitive habitats. Operations from boats will help reduce foot traffic in soft substrates and vegetation. Flushed oil must be recovered to prevent further oiling of adjacent areas. Should not be used directly on attached algae or in rich, intertidal areas.
Environmental Effects:	Hot water contact can kill attached animals and plants. If containment methods are not sufficient, oil may be flushed into adjacent areas. Flooding may cause sediment loss and erosion of the shoreline and shallow-rooted vegetation. Some trampling of substrate and biota will occur.
Waste Generation:	Depends on the effectiveness of the collection method.

High-pressure, Hot Water Flushing

Objective:	To mobilize weathered and viscous oil strongly adhered to surfaces.
Description:	Hot water (90°F [32°C] up to 171°F [77°C]) is sprayed with hand-held wands at pressures greater than 100 psi (720 kpa). If used without water flooding, this procedure requires immediate use of vacuum or sorbents to recover the oil/water runoff. When used with a flooding system, the oil is flushed to the water surface for collection by skimmers, vacuum, or sorbents.
Applicable Habitat Types:	Gravel substrates, bedrock, and man-made structures.
When to Use:	When oil has weathered to the point that warm water at low pressure no longer effectively removes oil. To remove viscous oil from man-made structures for aesthetic reasons.
Biological Constraints:	Use should be restricted so that the oil/water effluent does not drain across sensitive habitats (damage can result from exposure to oil, oiled sediments, and hot water). Should not be used directly on attached algae nor rich, intertidal areas. Released oil must be recovered to prevent further oiling of adjacent areas.
Environmental Effects:	All attached animals and plants in the direct spray zone will be removed or killed, even when used properly. Oiled sediment may be transported to shallow nearshore areas, contaminating them and burying benthic organisms.
Waste Generation:	Depends on the effectiveness of the collection method.

Steam Cleaning

Objective:	To remove heavy residual oil from solid substrates or man-made structures.
Description:	Steam or very hot water (171°F [77°C] to 212°F [100°C]) is sprayed with hand-held wands at high pressure (2,000+ psi [14,400 kpa]). Water volumes are very low compared to flushing methods.
Applicable Habitat Types:	Man-made structures such as seawalls and riprap.
When to Use:	When heavy oil residue must be removed for aesthetic reasons, when hot water flushing is not effective, and no living resources are present.
Biological Constraints:	Not to be used in areas of soft substrates, vegetation, nor high biological abundance directly on, nor below, the structure.
Environmental Effects:	Complete destruction of all organisms in the spray zone. Difficult to recover all released oil. If containment methods are not sufficient, oil may be flushed into nearshore areas.
Waste Generation:	Depends on the effectiveness of the collection method. Usually sorbents are used, generating significant waste volumes.

Sand Blasting

Objective:	To remove heavy residual oil from solid substrates or man-made structures.
Description:	Use of sandblasting equipment to remove oil from the substrate. May include recovery of used (oiled) sand.
Applicable Habitat Types:	On heavily oiled bedrock, artificial structures such as seawalls and riprap.
When to Use:	When heavy oil residue must be cleaned for aesthetic reasons, and even steam-cleaning is not effective.
Biological Constraints:	Not to be used in areas of soft substrates, vegetation, nor high biological abundance directly below, nor adjacent to, the structures.
Environmental Effects:	Complete destruction of all organisms in the blast zone. Possible smothering of organisms in adjacent areas. Unrecovered, used sand will introduce oiled sediments into the adjacent habitat. Oiled sediment may be transported to shallow nearshore areas, contaminating them and burying benthic organisms.
Waste Generation:	Will need to recover and dispose of oiled sand used in blasting.

Dispersants

Objective:	To reduce impact to sensitive shoreline habitats and animals that use the water surface by chemically dispersing oil into the water column.
Description:	Dispersants reduce the oil/water interfacial tension, making it easier for waves to break up oil into larger numbers of smaller particles. Also prevents dispersed particles from recoalescing and forming bigger, more buoyant droplets that float to the surface, re-creating sheens. Specially formulated products containing surface-active agents are sprayed (at concentrations of 1–5 percent by volume of the oil) from aircraft or boats onto the slicks. Some agitation is needed to achieve dispersion. Effectiveness diminishes as the oil spreads and weathers.
Applicable Habitat Types:	Water bodies with sufficient depth and volume for mixing and dilution.
When to Use:	When the impact of the floating oil has been determined to be greater than the impact of dispersed oil on the water-column and benthic community. Requires RRT approval for use.
Biological Constraints:	Use in shallow water could affect benthic resources. Consideration should be made to avoid directly spraying any wildlife, especially birds or fur-bearing marine mammals.
Environmental Effects:	Until sufficiently diluted, the dispersed oil can adversely impact organisms in the upper water column. Because dispersion may be only partially effective, some water-surface and shoreline impacts could occur.
Waste Generation:	None.

Emulsion-treating Agents

Objective:	To break or destabilize emulsified oil into separate oil and water phases. Also can be used to prevent emulsion formation, increasing oil recovery rates, extending the window for dispersant application, or making burning possible.
Description:	Emulsion-treating agents are surfactants that are applied to emulsified oil at low concentrations (0.1–2 percent). They can be injected into skimmer reservoirs to break the emulsion as it is skimmed from the water. They can be sprayed (similar to dispersants) directly onto slicks to break or prevent emulsions, although this type of application has been used only in field trials.
Applicable Habitat Types:	On all water environments.
When to Use:	To break emulsions in skimming systems, where storage capacities are very limited. To separate the recovered, emulsified oil and water so that the water can be treated and discharged. To break or prevent floating emulsions, where emulsified oil can reduce skimmer efficiency and dispersant effectiveness. Requires RRT approval for use.
Biological Constraints:	Very few products have toxicity data available, making it difficult to fully evaluate biological constraints. Use in shallow water could affect benthic resources. Responders should avoid directly spraying any wildlife, especially birds or fur-bearing marine mammals.

Emulsion-treating Agents (cont.)

Environmental Effects:	Because this is a new method, there is little data available to evaluate environmental effects. Effective dosages are one to two orders of magnitude lower than dispersants. Environmental concerns include the potential for increased oil content of separated water; whether the oil will be more readily dispersed; and how the treated oil will behave upon contact with skimming equipment, birds, mammals, and shorelines.
Waste Generation:	May enable recycling of oil/water mixtures by breaking down emulsions.

Elasticity Modifiers

Objective:	To impart visco-elastic properties to floating oil, thereby increasing skimming rates.
Description:	The liquid product is applied at a rate of 1:13 to 1:150 product:oil, depending on the oil type. Some mixing is required and is usually provided by the water spray during application. Treated oil is gelatinous, or semi-solid, but still fluid; there is no chemical change in the oil. The primary purpose is to increase skimmer efficiency removal rates while minimizing water recovery amounts. Increases the efficiency of some skimmers, but may clog other skimmers and pumps.
Applicable Habitat Types:	On all water environments where oil can be accessed for skimming. Not suitable for use near wetlands nor debris because of increased adhesive properties of the treated oil.
When to Use:	When skimmer efficiency is low. Must be used with booming or other physical containment. Ideal for thin slicks of No. 2 fuel oil or diesel that are very difficult to recover with mechanical equipment or sorbents. Requires RRT approval for use.
Biological Constraints:	Not suitable for vegetated shores nor where extensive debris is mixed in the oil. Should be avoided when birds or other wildlife cannot be kept away from the treated oil.
Environmental Effects:	May increase the smothering effect of oil on organisms; therefore, use should be considered only where recovery of the treated oil is likely.
Waste Generation:	If skimming efficiency is increased, will reduce the volume of water in oil/water collections. Effects on recycling of oil treated with elasticity modifiers is unknown.

Surface Collecting Agents

Objective:	To collect or herd oil into a smaller area and thicker slick in order to increase recovery. Can be used to herd oil away from sensitive areas or to help contain oil when it is necessary to move a boom.
Description:	These agents, which are insoluble surfactants and have a high spreading pressure, are applied in small quantities (1–2 gallons per lineal mile) to the clean water surrounding the edge of a fresh oil slick. They contain the oil, prevent spreading, but do not hold the spill in place. Hand-held or vessel-mounted systems can be used. Must be applied early in spill, when oil is still fluid.
Applicable Habitat Types:	On all still-water environments.
When to Use:	Potential use for collection and protection. For collection, used to push slicks out from under docks and piers where it has become trapped, or in harbors where the equipment is readily accessible for use early in the spill. For protection in low-current areas, used to push slicks away from sensitive resources such as wetlands. Not effective in fast currents, breaking waves, nor rainfall. Requires RRT approval for use.
Biological Constraints:	Not suitable for use in very shallow water nor fish-spawning areas.
Environmental Effects:	Direct acute toxicity to surface-layer organisms possible, though available products vary greatly in their aquatic toxicity.
Waste Generation:	Same as for manual oil recovery.

Solidifiers

Objective:	To change the physical state of spilled oil from a liquid to a solid.
Description:	Chemical agents (polymers) are applied to oil at rates of 10–50 percent or more, solidifying the oil in minutes to hours. Various broadcast systems, such as leaf blowers, water cannons, or fire suppression systems, can be modified to apply the loose granular product over large areas. Can be applied to both floating and stranded oil. Mixing is usually needed, and can be done with a strong water spray. Can be placed in booms, pads, pillows, and socks and used like sorbents.
Applicable Habitat Types:	All water environments, bedrock, sediments, and artificial structures.
When to Use:	To immobilize the oil or prevent refloating from a shoreline, penetration into the substrate, or further spreading. However, the oil may not fully solidify unless the product is well mixed with the oil, and may result in a mix of solid and untreated oil. Generally not used on heavy oil spills that are already viscous. Requires RRT approval for use.
Biological Constraints:	Must be able to recover all treated material.
Environmental Effects:	Products are insoluble and have very low aquatic toxicity. Unrecovered solidified oil may have longer impact because of slow weathering rates. Physical disturbance of habitat is likely during application and recovery on land.
Waste Generation:	If skimming efficiency is increased, solidifiers may reduce the volume of water collected during oil recovery. Oil treated with solidifiers is typically disposed of in landfills.

Surface Washing Agents

Objective:	To increase the efficiency of oil removal from contaminated substrates.
Description:	Special formulations are applied to the substrate, as a presoak and/or flushing solution, to soften or lift weathered or heavy oils from the substrate to enhance flushing methods. The intent is to lower the water temperature and pressure required to mobilize the oil from the substrate during flushing. Some agents will disperse the oil as it is washed off the beach, others will not.
Applicable Habitat Types:	On any habitat where water flooding and flushing procedures are applicable. Has been used to increase the removal of oil adhered to vegetation.
When to Use:	When the oil has weathered to the point where it cannot be removed using ambient water temperatures and low pressures. This approach may be most applicable where flushing effectiveness decreases as the oil weathers. Requires RRT approval for use.
Biological Constraints:	When the product does not disperse the oil into the water column, the released oil must be recovered from the water surface. Use should be restricted so that the oil/water effluent does not drain across sensitive habitats. Other concerns are where suspended sediment concentrations are high, near wetlands, and near sensitive nearshore resources.
Environmental Effects:	The toxicity and effects on dispersability of treated oil vary widely among products. Selection of a product should consider its toxicity.
Waste Generation:	Because treated oil must be recovered, waste generation is a function of recovery method, which often includes sorbents.

Nutrient Enrichment (Biostimulation)

Objective:	To accelerate the rate of hydrocarbon degradation due to natural microbial processes by exploiting ability of microorganisms to convert hydrocarbons to carbon dioxide, water, and innocuous by-products.
Description:	Liquid products are diluted in water and applied with spray or injection systems. Dry products may be applied by hand or powder spray systems. Oleophilic fertilizers are sprayed neat directly on the oiled surface. The frequency of nutrient addition is determined by monitoring porewater so that nitrate-N concentrations are in the range of ~2–10 mg/L. Regular tilling or other means of aeration may be needed to maintain minimum oxygen levels, break up the oil residues, and provide mixing of the nutrients with the oiled sediments.
Applicable Habitat Types:	Could be used on any shoreline habitat type where access is allowed and nutrients are deficient.
When to Use:	Only when nutrients are limiting the rates of natural biodegradation. On moderate- to heavily-oiled substrates, after other techniques have been used to remove free product; on lightly-oiled shorelines, where other techniques are destructive or ineffective; and where nutrients limit natural attenuation. Most effective on light to medium crude oils and fuel oils. Less effective where oil residues are thick. Not considered for gasoline spills, which evaporate rapidly. Biodegradation of hydrocarbons requires: oil-degrading microbes, nutrients (nitrogen and phosphorus), oxygen, moisture, and time, any one of which can be limiting. Requires RRT approval for use.

Nutrient Enrichment (Biostimulation) (cont.)

Biological Constraints:	Avoid using ammonium-based fertilizers adjacent to waterbodies because un-ionized ammonia is toxic to aquatic life at very low levels. Nitrate is just as good a nitrogen source without the ecotoxicity. If nutrients are applied properly with adequate monitoring, eutrophication should not be a problem. Only nutrient additives proven to be nontoxic and effective in either the laboratory or the field should be used in the environment. Check fertilizers for their metal content since some common fertilizers contain relatively high levels of metals. Contact toxicity of oleophilic nutrients may restrict their use, as other chemicals in the product could be more toxic to aquatic organisms in the presence of oil.
Environmental Effects:	Detrimental effects to shoreline from foot or vehicle traffic caused by workers applying nutrients (unless nutrients are sprayed from a vessel or aircraft).
Waste Generation:	None.

Natural Microbe Seeding (Bioaugmentation)

Objective: A form of bioremediation used to accelerate natural microbial degradation of oil by adding high numbers of oil-degrading microorganisms to accelerate the process.

Description: Formulations containing specific hydrocarbon-degrading microbes are added to the oiled area because there are few indigenous hydrocarbon degraders, or those that are present cannot degrade the oil effectively. Since microbes require nitrogen and phosphorus to convert hydrocarbons to biomass, formulations containing these oil degraders must also contain adequate nutrients. Bioaugmentation has not been demonstrated in the scientific literature to be effective on oil spills when applied in the field.

Bioaugmentation appears less effective than biostimulation because: 1) hydrocarbon degraders are ubiquitous in nature and, when an oil spill occurs, the influx of oil will cause an immediate increased response in the hydrocarbon-degrading populations; but, 2) if nutrients are in limited supply, the rate of oil biodegradation will be less than optimal; thus, 3) supplying nutrients will enhance the process initiated by the spill, but adding microorganisms will not, because they still lack the necessary nitrogen and phosphorus to support growth.

The maximum number of microbial organisms achievable will determine the maximum biodegradation rate. If nutrient supplementation is sufficient to maximize that rate, bioaugmentation will not further increase the biodegradation rate.

Natural Microbe Seeding (Bioaugmentation) (cont.)

Applicable Habitat Types:	There is insufficient information on impacts or effectiveness of this method to make a judgment on applicable habitat.
When to Use:	There is insufficient information on impacts or effectiveness of this method to make a judgment on when to use it. Requires RRT approval for use.
Biological Constraints:	Avoid using ammonium-based fertilizers adjacent to waterbodies because un-ionized ammonia is toxic to aquatic life at very low levels. Nitrate is just as good a nitrogen source without the ecotoxicity. If the product containing nutrients is applied properly with adequate monitoring, eutrophication should not be a problem, but toxicity tests should be evaluated carefully, as other chemicals in the product could be toxic to aquatic organisms.
Environmental Effects:	Detrimental physical effects to shoreline from foot or vehicle traffic caused by workers applying bioaugmentation products (unless nutrients are sprayed from a vessel or aircraft).
Waste Generation:	None.

In-situ Burning

Objective:	To remove oil from the water surface or habitat by burning the oil in place.
Description:	Oil floating on the water surface is collected into slicks at least 1–2 mm thick and ignited. The oil can be contained in fire-resistant booms, or by natural barriers such as ice or the shore. On land, oil can be burned when it is on a combustible substrate such as vegetation, logs, and other debris. Oil can be burned from non-flammable substrates using a burn promoter. On sedimentary substrates, it may be necessary to dig trenches for oil to accumulate in pools to a thickness that will sustain burning. Heavy oils are hard to ignite but can sustain a burn. Emulsified oils may not ignite nor sustain a burn when the water content is greater than 25 percent. For oils where sinking of the burn residue is of concern, it may be possible to collect the burn residues while they are still hot and buoyant by using nets deployed under the burn.
Applicable Habitat Types:	On most habitats, except dry, muddy substrates where heat may impact the biological productivity of the habitat. May increase oil penetration in permeable substrates. Not suitable for woody vegetation such as mangroves.
When to Use:	On floating slicks, early in the spill event when the oil can be kept thick enough to sustain the burn. On land, where there is heavy oil in sites neither amenable nor accessible to physical removal and the oil must be removed quickly. Removal rates of 50,000 gal/hour can be achieved for a burn area of 10,000 ft^2; under prime conditions, removal efficiencies can exceed 90%. In vegetated and mud habitats, a water layer will minimize impacts to sediments and roots. Many potential applications for spills in ice. There are many operational and public health limitations. Requires RRT approval for use.

In-situ Burning (cont.)

Biological Constraints:	All biota in the burn area will be impacted. The possible effects of large volumes of smoke on nesting birds and populated areas should be evaluated.
Environmental Effects:	Temperature and air quality effects are likely to be localized and short-lived. Toxicological impacts from burn residues have not been evaluated.
	On water, burn residues may sink. Recent studies have predicted that about half of international crude oils would tend to sink in seawater, but only after cooling. On land, removal of burn residues is often necessary for crude and heavy oils. Residue removal can physically disrupt sensitive habitats such as marshes. There are several studies on the relative effects of burning oiled marshes compared to other techniques or natural recovery. Laboratory and field studies indicate recovery of wetland vegetation will depend on season of burn, type of vegetation, and water level in the marsh at time of burn.
Waste Generation:	Any residues remaining after burning will need to be collected and landfilled but, with an efficient burn, will be a small fraction of the original oil volume

1 Introduction

1.1 Introduction

1

This field manual is intended for use by responders at an oil spill. It is a collection of "Rules of Thumb" and checklists that provide quick access to the information needed when formulating response strategies.

The manual is neither an all-inclusive textbook nor a substitute for training, qualified technical advice, or common sense. It addresses response to oil spills that could reach water and those that occur on land. Legal issues and environmental regulations are likewise outside the scope of this manual.

This manual is not a statement of ExxonMobil policy. However, all operations, including selection of response strategies, access to shorelines, implementation of cleaning methods, etc., planned or conducted on behalf of ExxonMobil are to be in full compliance with applicable laws and regulations. Exxon Mobil Corporation, its affiliates, subsidiaries, employees, officers, directors, and contractors shall not be held liable for injury, loss, or damage incurred as the result of use of this manual by others.

Additionally, this manual remains a work in progress and ExxonMobil retains the right to modify the individual sections as it deems necessary. The manual is drafted in English. ExxonMobil bears no responsibility for misinterpretation or other distinctions resulting from translation.

ExxonMobil permits the use and modification of this manual provided that all modifications are clearly denoted and that the user/modifier acknowledges that ExxonMobil retains the right to use and copy all derivative works at its discretion. Proper acknowledgement of copyright ownership by ExxonMobil is required.

1.2 Organization of Manual

This introductory section explains the organization of the manual and discusses some general oil spill response principles.

The remainder of the manual is organized according to the sequence of events encountered in a well-organized oil spill response. Table 1-1 contains a brief description of each section and Table 1-2 lists the steps to be taken in a spill response and the corresponding manual sections. Each step involves either a direct action or an issue that can be resolved by an action that is described in the manual.

It is important to realize that oil spill response should be considered in terms of the total package or system and that the individual components of the system should be considered collectively rather than independently.

Table 1-1 Description of the Manual Contents

Section	Description of Contents
2	Provides health and safety precautions for those involved in responding to a spill.
3	Provides guidance on dealing with logistics and communication requirements.
4	Provides information on the fate of oil spills on water and provides recommendations for surveillance and tracking of slicks.
5	Provides performance information for selecting a type and size of boom for specific applications.
6	Provides techniques for protecting shorelines which are threatened but not yet impacted by an oil spill.
7	Provides information on the proper selection and use of chemical dispersants.
8	Provides information on removing oil by in-situ burning.
9	Discusses selection and use of skimmers as a tool for mechanical cleanup and recovery.
10	Discusses the selection and use of sorbent materials in oil spill cleanup operations.
11	Discusses the selection and use of transfer equipment.
12	Provides guidance on shoreline cleanup programs including the evaluation of the impact of the cleanup procedure and determination of the support needed for each cleanup technique.
13	Discusses wildlife rescue and rehabilitation, including oiled birds and mammals.
14	Discusses waste management alternatives including storage and disposal of oily water, debris, sorbent materials, cleaning gear, etc.
15	Discusses issues relevant to response in cold regions.
16	Provides general guidance on support that aerial assets can provide.
Ref	Provides a list of selected references for more detailed information.

Table 1-2 Spill Response Activities

Step	Activities	Section
1	Activate response operations: • Act safely • Plan logistics and communications	 2, 15 3
2	Obtain and assess incident data: • Spill location • Oil type and volume • Weather and sea conditions	 4, 16
3	Monitor the spill – conduct surveillance and tracking	4, 16
4	Contain and remove the oil: • Mechanical containment and recovery • Chemical dispersion • In-situ burning	16 5, 9, 10, 11, 15 7, 15 8, 15
5	Protect threatened resources: • Shoreline • Wildlife	 6 13
6	Evaluate wildlife rehabilitation options	13
7	Conduct shoreline treatment	12, 15, 16
8	Finalize operations: • Dispose of wastes • Demobilize personnel and equipment	 14

1.3 Response Priorities

Response objectives, in general, are in the following order:

- Protecting the safety and health of responders and the public
- Reducing the impact to the environment
- Protecting property

Safety and health are the highest priorities.

The following factors should be considered:

- Fire and explosion potential of vapors at or near the spill site
- Potential adverse effects of the oil
- Safe handling of chemicals used in countermeasures
- Proper use of safety equipment
- Heat stress/stroke or hypothermia
- Small boat safety
- Helicopter and aircraft safety
- Management of volunteers

Speed is essential in recovery efforts.

- Oil spreads and drifts rapidly; containment and recovery will be more effective if carried out before oil spreads over wide areas.
- Evaporation rapidly increases oil viscosity.
- Chemical dispersants are more effective when oil is minimally weathered.
- Oil can be burned more readily when fresh.
- Sustained combustion requires at least 0.1 inch (2–3 mm) of slick thickness.

1.4 Three-Tiered Response Consideration

Although every spill is unique, the consideration of discharge volume, location, and possible impacts allows spill events to be categorized according to three tiers.

Table 1-3 Three-Tiered Response

Tier 1	Accidental discharges occurring at or near a vessel or facility as a result of disruption in routine operations. Impacts are low and in-house response capability is adequate.
Tier 2	Medium-size spills occurring within the vicinity of vessel or facility as a consequence of a non-routine event. Significant impacts are possible and external (regional) support for adequate spill response, e.g., assistance from a local spill cleanup co-operative, is required.
Tier 3	Large spills occurring either near or remote from a vessel or facility as a result of a non-routine event, requiring substantial resources and support from national or worldwide spill co-operatives to mitigate effects perceived to be wide-reaching, i.e., spills of national or international significance.

Examples of Tier 1 spills include:

- Overflow of sumps or oil-water separators
- Leakage or overflow of tanks
- Leakage from valves, pipelines or transfer hoses
- Accidental discharge of bilge water from vessels
- Tank truck/tank car rollover near water

Examples of Tier 2 and 3 spills include:

- Cargo loss due to tanker grounding, collision, or system failure
- Rupture of a sub-sea pipeline
- Spills due to fire or explosion at a terminal or on a tanker
- Spills due to sabotage, natural disaster, or blowout
- Tank collapse near water

The tiered response approach calls for the smallest spills to be handled using local resources and plans. Additional tiers are activated as the available operational capability is exceeded. A possible organizational structure for a Tier 2 response is shown in Figure 1-1. It should be noted that some countries follow a prescribed organizational structure such as the US Incident Command System (ICS). Figure 1-1, therefore, is presented as an example only.

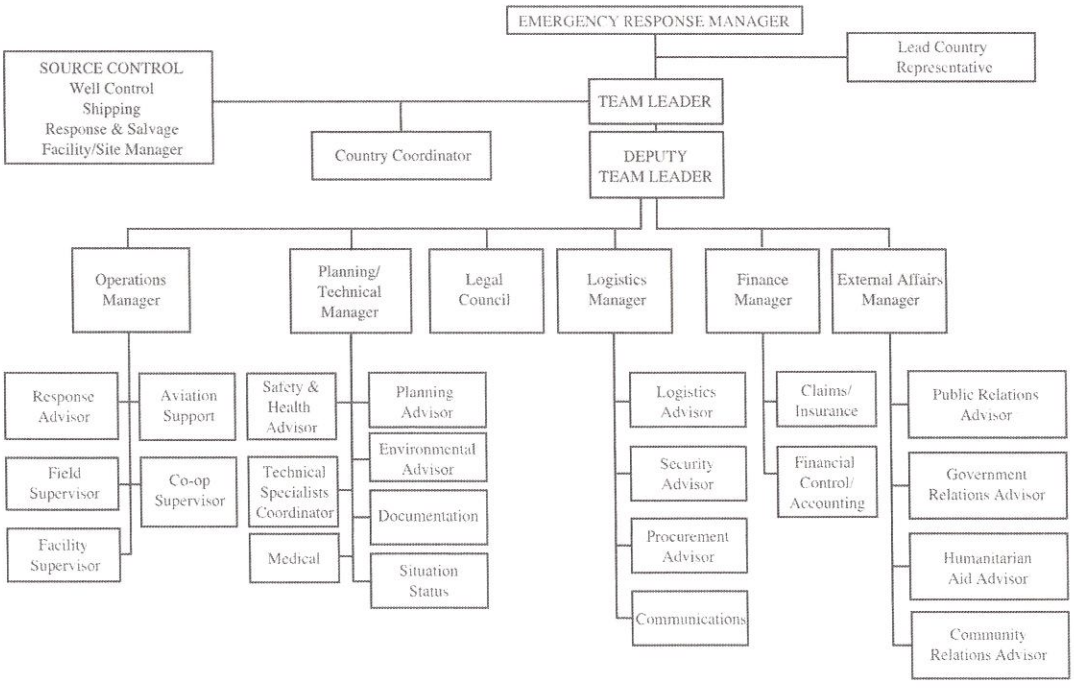

Figure 1-1 Example Organization Chart of a Spill Response Team

1.5 Personnel Requirements

The amount and type of oil-impacted shorelines are the prime factors that determine personnel requirements.

Useful rules of thumb for planning response operations are:

- Land-based operations (cleanup of shoreline) are much more labor intensive than sea-based operations (booming and skimming, in situ burning, or dispersant application)
- Peak personnel needs may occur several weeks into the spill response
- Optimal field operations supervision ratios are 1 supervisor: 10 foremen: 100 workers
- Supervisors must be in direct communication with the Operations Manager or a designated assistant

Figures 1-2 through 1-6 illustrate personnel requirements and time required for historical clean-up operations. Shoreline impact has a sizable impact on the workforce.

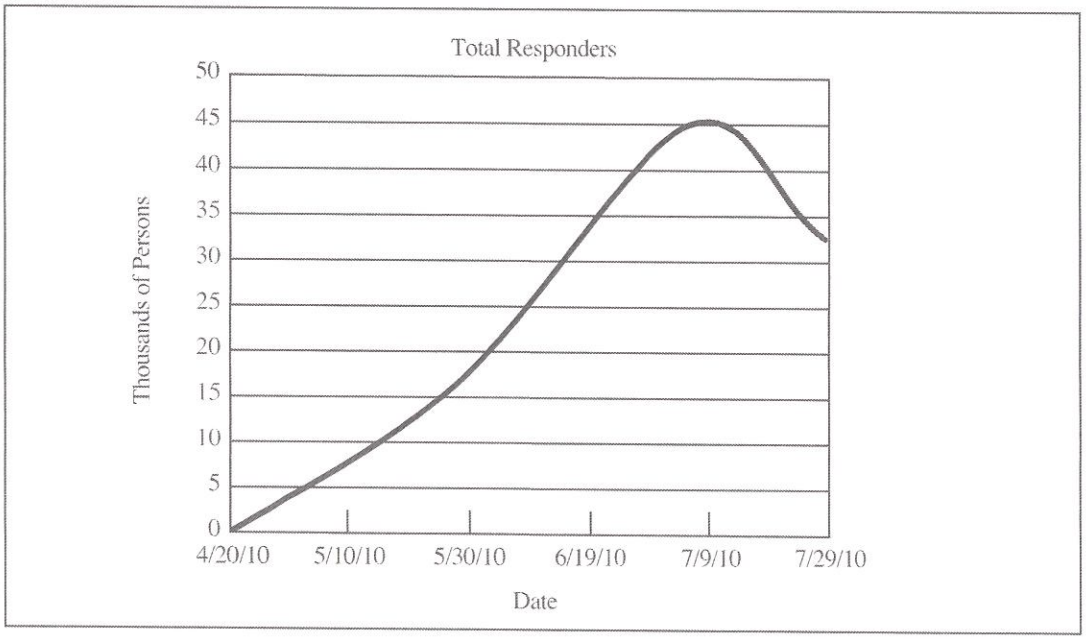

*Figure 1-2 Total Responders Involved in **BP Macondo** Incident through July 2010*

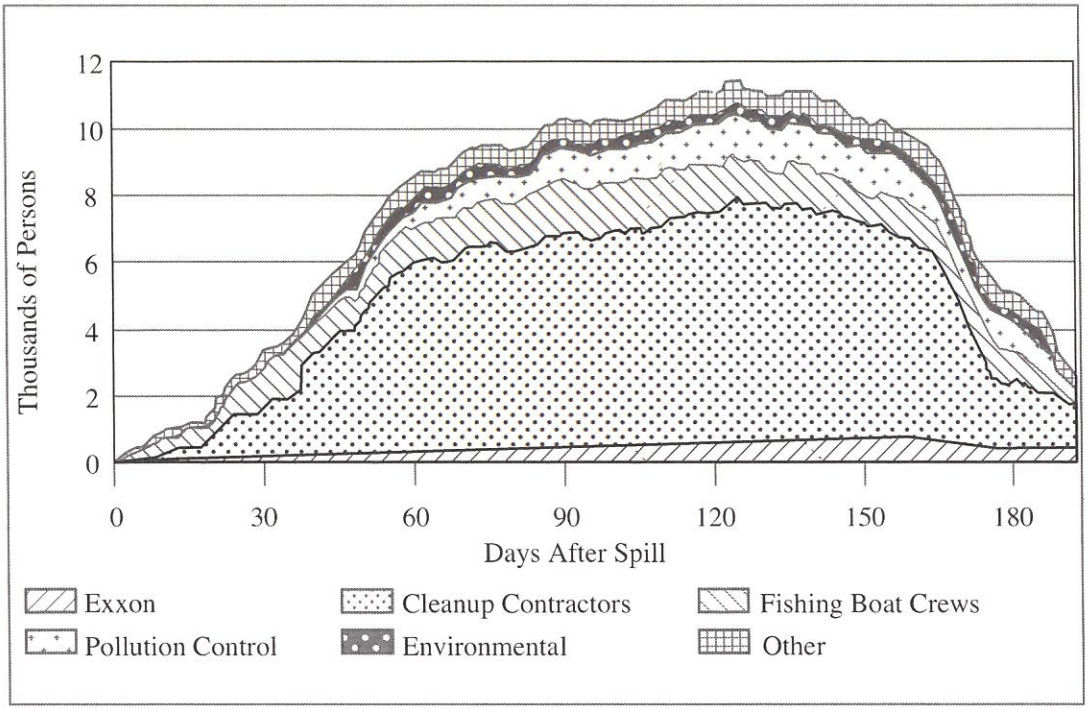

*Figure 1-3 Personnel Involved in the **Exxon Valdez** Spill*

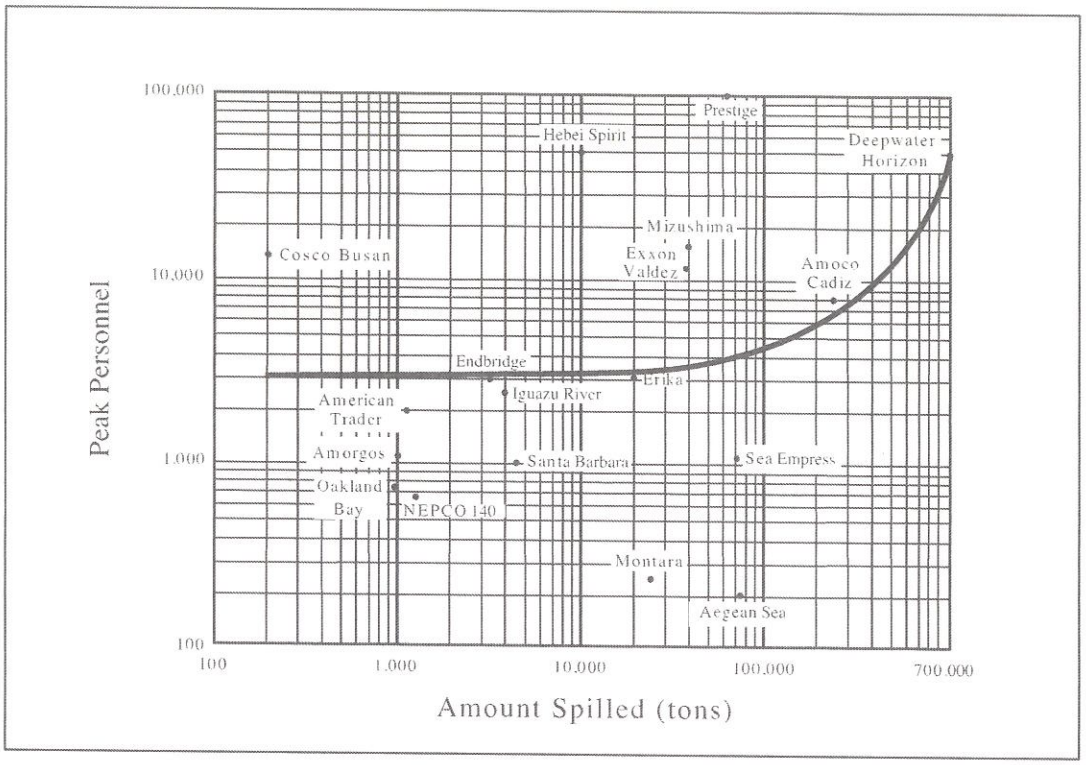

Figure 1-5 Peak Personnel Versus Amount Spilled

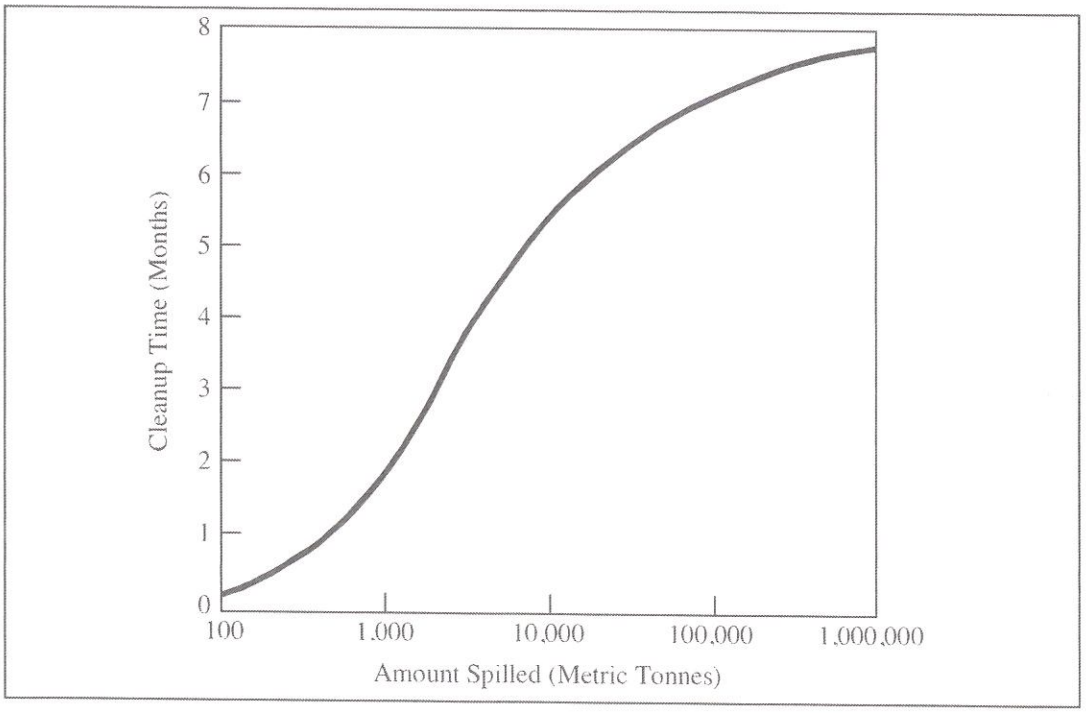

Figure 1-6 Spill Size Versus Duration of Cleanup

1.6 Critical Spill/Environmental Information

Once an oil spill has occurred, every attempt should be made to contain the spill immediately to prevent it from spreading. The most accurate information on the spill size, location, and environmental factors must be available to the on-scene management team.

The Oil Spill Data Log illustrated in Figure 1-7 is the primary source of information for predicting slick movement, behavior, and environmental impact.

The weather, oceanographic data, oil movement and impacts should be updated regularly.

- Report the logged information to the spill modeling team
- When specific information is not available, make a best estimate

OIL SPILL DATA LOG

Company: _____

Observer and Phone Number: _____

Date: _____ Time: _____

SPILL DATA

Crude or Product Type: _____

API Gravity: _____

Volume of Discharge: (est.) _____

Location of Initial Spill

- Latitude: _____ Longitude: _____

Direction of Slick Movement: _____

Size and Location of Slick(s): (Plot on Separate Sheets)

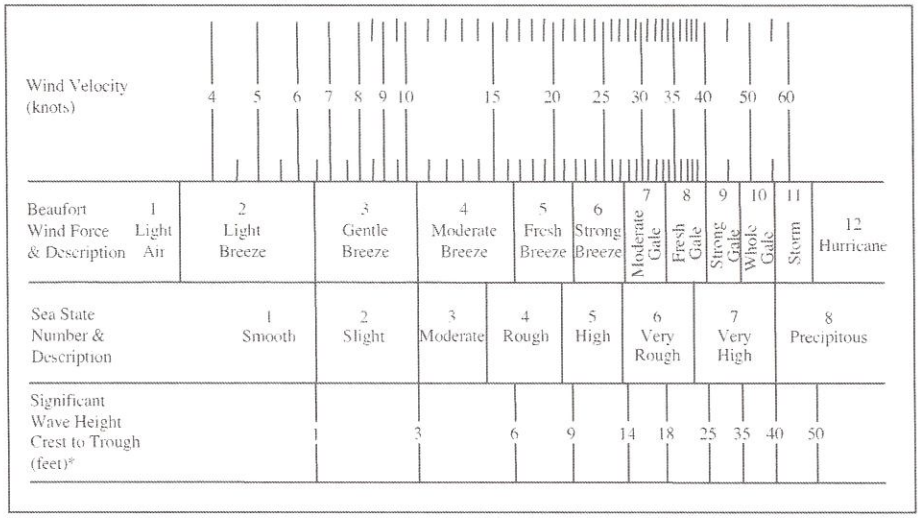
Figure 1-7 Oil Spill Data Log

Figure 1-8 shows the relationship between wind and wave conditions in fully developed seas. Beaufort wind force scale and sea state are shown relative to wind speed and wave height.



* The average height of the highest 1/3 of the waves, assuming 1000 mile (1600 km) fetch, 25-hour duration, Bretschneider Spectrum

*The average height of the highest 1/3 of the waves, assuming 1000 mile (1600 km) fetch, 25 hour duration, Bretschneider Spectrum

Figure 1-8 Related Wind and Wave Conditions in Fully Developed Seas

Oil spreading is complicated by the variability and interdependence of factors such as:

- Initial composition
- Weathering (includes the effects of evaporation, natural dispersion, and emulsification)
- Environmental conditions

Several oil spill models are available to predict the spreading of an oil slick, but good input data are necessary.

One algorithm used in several computerized models to describe the spreading was developed by Mackay et al. in 1980 (see References). The algorithm assumes the slick consists of a "thin" slick (i.e., sheen) and a thick slick, with the thick slick comprising about 90% of the total slick area. The thick slick feeds the thin slick at a rate dependent on empirically based constants. An average thickness of the thick part of a slick over a two day timeframe is plotted in Figure 1-9 for a medium crude in calm seas and low winds.

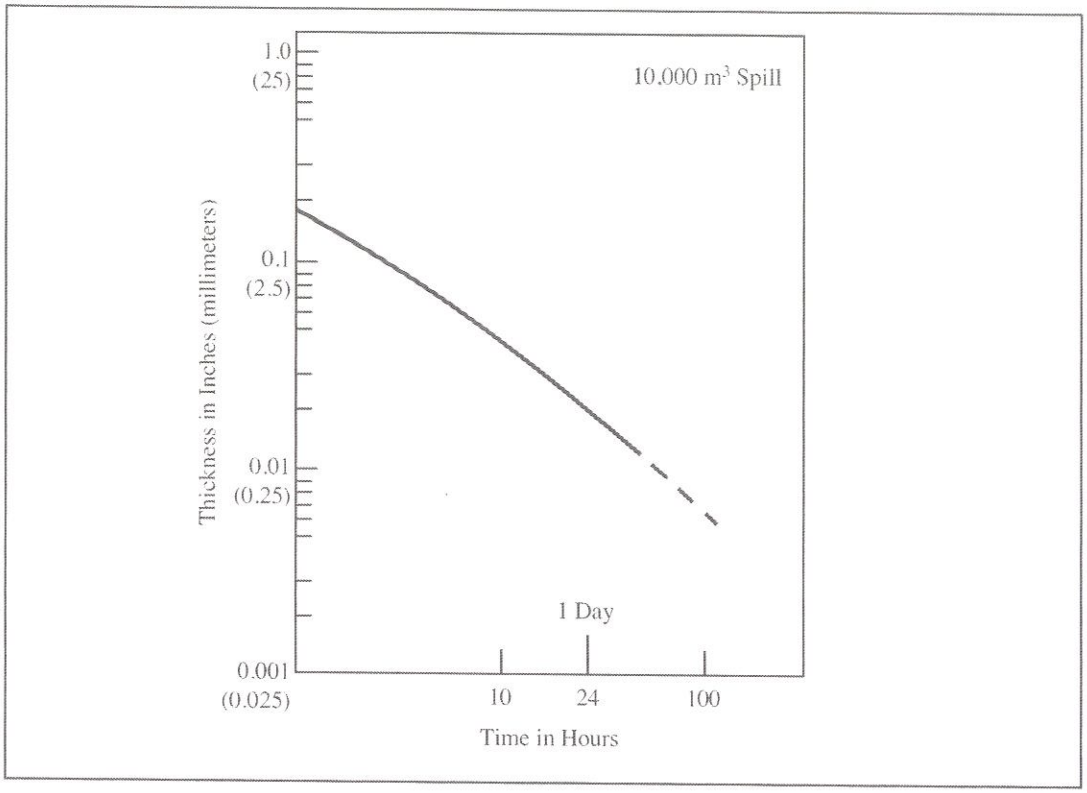


Figure 1-9 Behavior of the Thick Part of a Slick of Crude Oil on Water (Modified from Mackay et al., Oil Spill Processes and Models, University of Toronto. Figure 1-9 is based on the first 48 hours of concentric thick and thin slicks of medium crude under calm seas and low winds.)

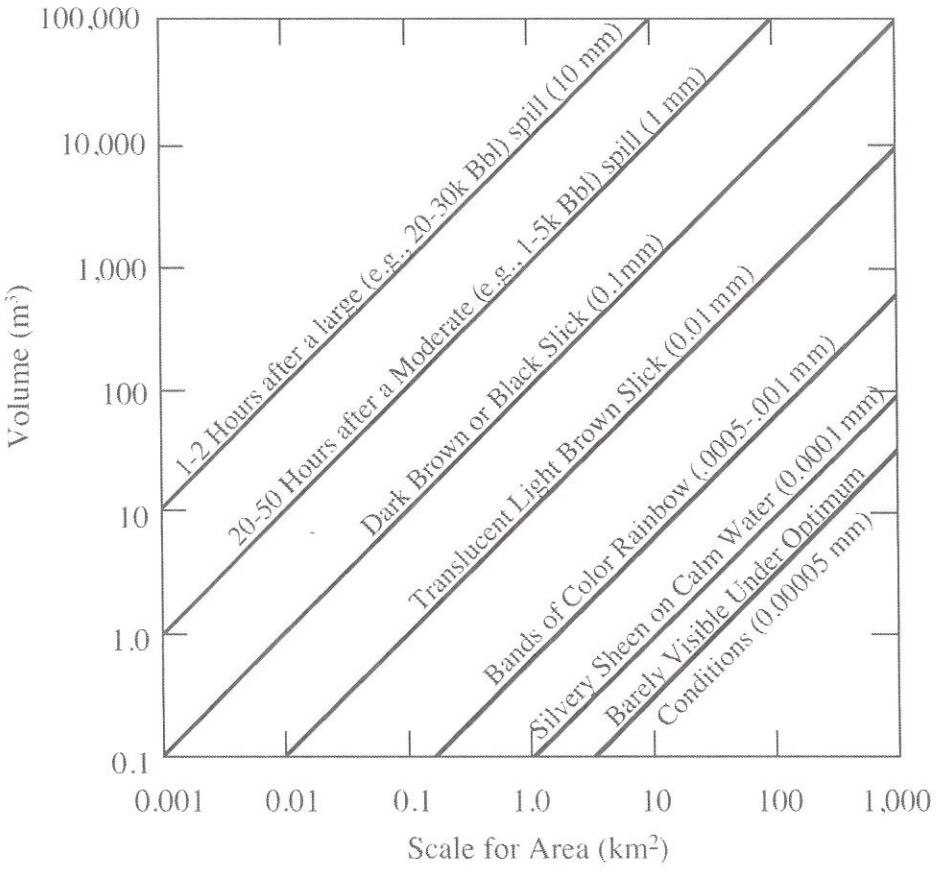
Figure 1-9 is intended to only show the predicted trend of thickness in a hypothetical spill with time. In general, spill thickness varies within a slick (even in the thick portion of the slick) and is dependent on the volume of oil spilled, wind/wave/current conditions, type of oil spilled, and water temperature. At present there is no means for measuring spill thickness over a large area. The most common means of assessing slick thickness is by visual color comparison as shown in Figure 1-10. The figure allows a gross estimate of spill volume to be made from color and area covered. The method has high error and caution should be used in using this tool for estimating how much oil was spilled. Table 1-4 is an alternative guide. Different crudes or weathering may lead to deviations from these average predictions.

In forecasting oil slick movement on water and probable coastal impact sites, note the following:

- Oil spill modeling is preferred to manual calculations
- In the absence of a computer model, slick movement may be predicted by vector addition of the components due to wind and current

- Currents dominate slick movement when winds are light
- The wind-driven velocity component of a slick is about 3–5% of wind speed and in the same direction as the wind
- The current-driven velocity component of a slick is co-directional with the current and at the same speed

• Never accept predictions blindly. Always verify by aerial reconnaissance and ground truthing



Conversion Factors
1 m^3 = 6.25 Bbl

Figure 1-10 Volume of a Slick of Crude Oil on Water

*Table 1-4 Determining Amount of Oil Remaining by Appearance**

	Appearance/Approximate Thickness					
	Barely Discernible	**Silvery Sheen**	**Rainbow Colors**	**Darkening Bands of Color**	**Dull Colors**	**Light Brown**
Approximate Thickness (Microns)	**0.05**	**0.1**	**0.5**	**1**	**3**	**10**
Area (m^2)	**Liters**					
100	<.01	.01	.05	.1	.3	1
1,000	.05	.1	.5	1	3	10
5,000	.25	.5	2.5	5	1.5	50
10,000 (1 hectare)	.5	1	5	10	30	100
100,000	5	10	50	100	300	1000
500,000	25	50	250	500	1500	5000
1,000,000 (1 km^2)	50	100	500	1000	3000	10000

* Based on numerous literature sources.
1000 microns = 1 millimeter; 1 micron thick is equivalent to 1 m^3 / km^2
Note: Area of a spill is arrived at by multiplying the estimated length of the spill by estimated width.
Examples: 1000 m x 1000 m = 1 km^2

1.7 Oil Spill Volume

Estimates of oil volume obtained from the color and size of a slick on water (see Figure 1-10 and Table 1-4) have large uncertainties associated with them due to:

- Variable oil properties
- The complexity of the slick geometry (spatial and temporal variability)
- Meteorological conditions
- Sea state
- Weathering
- Physical/chemical processes occurring within the slick

The thicknesses reported in Table 1-4 represent averages reported in the literature. For each of the appearance categories, a wide range of thicknesses has been reported, up to an order of magnitude different, as summarized in Table 1-5. The Bonn Agreement Oil Appearance Code, summarized in Table 1-5, is another way to estimate slick thickness and volume. A more detailed description of the Oil Appearance Code is provided in the 2009 Bonn Agreement Aerial Operations Handbook. These thicknesses should not be used for estimating the amount spilled except for very coarse estimates. This is especially true for spills that have been on water for some period of time and have lost volatile components, particularly if the oil is very light.

Table 1-5 Bonn Agreement Oil Appearance Code

Code	Description Appearance	Layer Thickness Interval (µm)	Liters per km^2
1	Sheen (silvery/grey)	0.04 to 0.30	40 to 300
2	Rainbow	0.03 to 5.0	300 to 5,000
3	Metallic	5.0 to 50	5,000 to 50,000
4	Discontinuous True Oil Color	50 to 200	50,000 to 200,000
5	Continuous True Oil Color	Greater than 200	Greater than 200,000

Observer experience will also have a marked effect on the accuracy of the estimate. The most accurate assessments of the quantity spilled can be made by accounting for losses from a vessel. If the type of oil is known as well as the time since spill, some computer programs can be very helpful in estimating the amount remaining. The volume of oil from an unlimited or unknown source may also be estimated from the areal extent and color of the slick.

- Slick thickness varies considerably, especially where it appears dark brown or black
- Most of the oil is located in areas where the slick appears brown or black
- Colored bands indicate an extremely thin slick of less than 1 micron or 0.001 mm

1.8 Oil Characteristics and Behavior

Table 1-6 summarizes the main physical/chemical properties, behavioral characteristics and adverse effects of various types of oil in seawater.

Table 1-6 Physical/Chemical Properties and Possible Adverse Effects of Common Oil Types During Spills

Oil Type	Physical/Chemical Properties	Adverse Effects on Environment
Light to volatile oils	• Spread rapidly • Tend to form unstable emulsions • High evaporation and solubility • May penetrate substrate • Removed from surfaces by agitation and low-pressure flushing	• Toxicity is related to the type and concentration of aromatic fractions: 1) naphthalene, 2) benzene • Toxicity of aromatic fractions depends on their biological half-lives in different species • Toxic to biota when fresh • Mangroves and marsh plants may be chronically affected due to penetration and persistence of aromatic compounds in sediments
Moderate to heavy oils	• Moderate to high viscosity • Tend to form stable emulsions under high energy marine environments • Penetration depends on substrate particle size • Weathered residue may sink and be absorbed by sediment • Immiscibility assists in separation from water • Weather to tar balls	• Adverse effects in marine organisms result from chemical toxicity and smothering • Toxicity depends on size of light fraction • Toxic effects reduced in tropical climates due to rapid evaporation and weathering • Low toxicity residue tends to smother plants or animals • Light fractions contaminate interstitial waters
Asphalt, #6 fuel-oil, Bunker C, waste oil	• Form tar balls at ambient temperatures • Resist spreading and may sink • May soften and flow when exposed to sunlight • Very difficult to recover from the water • Easy to remove manually from beach surface with conventional equipment	• Immediate and delayed adverse effects due to small aromatic fractions and smothering • Most toxic effects due to incorporation in sediment • Absorption of radiated heat places thermal stress on the environment • Lower toxicity to marine plants than mobile animals

The chemical and physical properties of the spilled oil and ambient conditions will determine how the oil will behave. The basic processes and their time frames are shown in Figure 1-11.

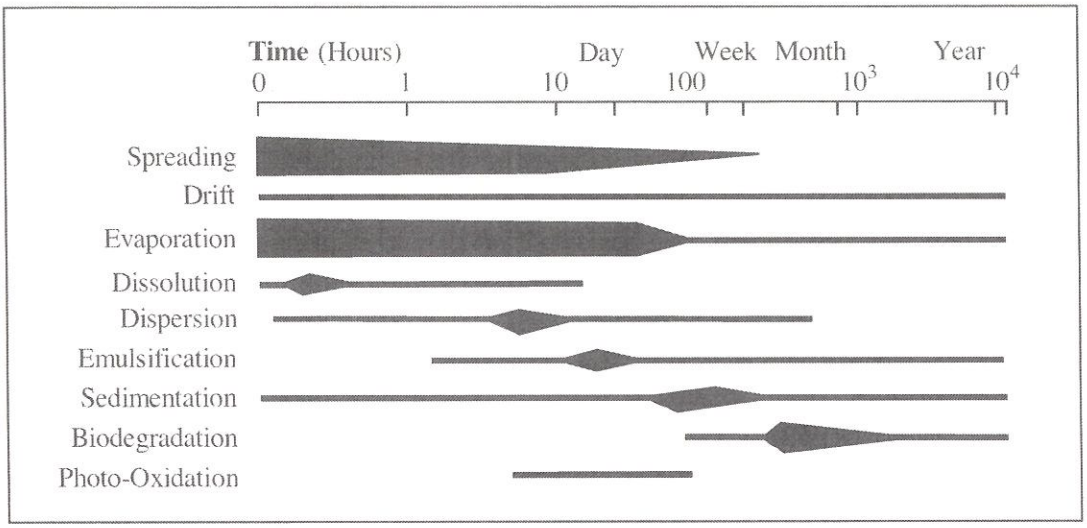


Figure 1-11 Processes Versus Time Elapsed Since the Spill

1.9 Limiting Access

A good contingency plan prepared for the area involved in a spill should identify the type of ecological or other constraints in the area addressed. Even if all of the types of constraints are identified, however, some of the actual restrictions may vary from year to year (e.g., nesting location of threatened species). Periods when transit through such areas or when cleanup can proceed will be apparent by noting other periods of high threat to resources. In defining constraints, data should be collected on:

- Resources affected
- The reason for restrictions on access (usage)
- The start and end dates for the restriction
- The activities that can continue during the restriction

Some restrictions may extend some distance away from the object or area to be protected. Maps may need to be prepared showing areas to be avoided while transporting survey teams or response workers to the spill site from remote bases.

1.10 Net Environmental Benefit Analysis

A process known as Net Environmental Benefit Analysis (NEBA) considers the advantages and disadvantages of oil spill response options in terms of their respective impacts on the environment. NEBA recognizes that cleanup responses have the potential to cause negative environmental impacts but may be justifiable because of overriding benefits and/or the avoidance of further impacts. An effective Net Environmental Benefit Analysis is a three-step process (Table 1-7).

Table 1-7 Net Environmental Benefit Analysis

Step	Activities
1	Identify and prioritize an area's ecological, socioeconomic, and cultural resources according to environmental sensitivity.
2	Evaluate feasible response options and compare them not only to each other but also to the option of natural recovery in order to define environmental benefits and drawbacks for all options.
3	Select the response option or combination of options that result in the greatest environmental benefit and/or least adverse effects on key resources.

The NEBA process can be applied to offshore, nearshore and inland spill response, and to shoreline cleanup. The following example considers offshore response:

Step 1 After identifying the resources in all possible directions that oil might reach, it is determined that slicks could strand in a productive mangrove.

Step 2 Options to prevent or reduce impacts to the mangrove include dispersants, mechanical cleanup and recovery, in-situ burning, and natural dispersion of the oil at sea.

Because the mangrove will be oiled with likely lethal effects if no action is taken, it is decided that natural dispersion/recovery is not an option.

Mechanical recovery, while it may be the least intrusive, is not efficient and likely to allow some oil to reach the mangroves. In-situ burning is also determined to be of limited efficiency. Dispersants, while they may have a short-duration negative effect on some marine organisms, are much more efficient at keeping oil from adhering to the mangroves, and will minimize the impacts to the mangroves, resulting in clear net environmental benefit.

Step 3 Dispersant application is selected as the preferred option.

Net environmental benefit should always be a key factor when making decisions on the optimum spill response options to implement.

2 Safety and Health

2.1 Introduction

2

Protection of human safety and health is a fundamental objective of any ExxonMobil operation. Safe work practices help to minimize safety and health risks to responders and the surrounding community. Limiting access to affected areas is important to protect the public from exposure to spilled oil or interaction with response equipment. In addition to being familiar with the basic safety and health procedures outlined in this section, workers should refer to the site safety and health plan as well as company safety manuals and regional response plans for additional information.

2.1.1 Basic Safety Rules

Training is a key element in maintaining worker health and safety. In some countries training, such as HAZWOPER in the US, is mandatory. All response workers should have basic oil spill response safety training including, but not limited to:

- Site-specific safety and health rules
- Emergency procedures

The following basic safety and health rules should be followed by all spill response workers:

- Consider the potential safety and health hazards of each spill situation.
- Respond in teams, i.e., use the "buddy system".
- Incorporate safety and health risk evaluations into all actions.
- Obtain health hazard data from the supporting industrial hygiene/safety/ and/or medical personnel.
- Refrain from working in environments that exceed your training and/or capability.
- Always inform someone of your intended destination and the estimated time of your return.
- Refrain from entering or traveling in spill areas unnecessarily.
- Avoid skin contact with spilled material and use gloves and the protective clothing provided.
- Do not rely on your senses (e.g., smell) to determine hazardous conditions. Use detection devices.

2.1.2 The Buddy System

To provide a flexible and safe approach for response workers, a "buddy system" should be used during all response efforts. The minimum response team should include two people who perform the activity within direct line of sight of a third person who has communication or personnel resources to effect a "rescue", if required.

The "buddy system" does not apply to equipment or process spills that can be controlled by one person using common equipment (e.g., valve leaks).

2.1.3 Hand or Whole Body Communication Signals

Verbal communication while wearing respirators is difficult because speech is muffled and distorted by the facemask. A set of hand or whole body communication signals known to all personnel is essential for working safely. Some of these emergency communication signals are listed in Table 2-1.

Table 2-1 Emergency Communication Signals

Signal	Meaning
Hand clutching throat	I am out of air!
Hands on top of head	I need assistance!
Thumbs up	Okay! I am all right. I understand.
Thumbs down	No! Negative!
Grip partner's wrist or place both hands around partner's waist.	Leave area immediately!

2.2 Risks

The potential safety and health risks associated with oil spill response efforts include:

- Fire and explosion
- Hazardous atmospheres/hazardous chemicals
- Slips, trips and falls
- Demanding physical activities under possibly adverse climatic and site conditions

2.2.1 Fire and Explosions

A major safety risk during crude oil or refined product spill response is from fire or explosions. This risk is site and substance specific and must be evaluated before response personnel enter a spill area or damaged vessel/equipment. Explosions present a physical risk from:

- Burns
- Flying debris
- Atmospheric over-pressure

Burning hydrocarbons result in a variety of combustion products. Therefore, only experienced personnel with proper safety, respiratory protection and hazard detection equipment should approach a burning vessel or spilled material. Remember:

- Always approach from the upwind, upstream, or uphill side, if possible.
- Retreat if heat intensity is severe or material is spreading.

When preparing to work in a potentially hazardous area, personnel should:

- Assess the need to enter the area.
- Determine the fire hazard potential of the material or mixture spilled.
- Be alert to possible oxygen deficiency.
- Obtain a combustible gas/oxygen meter that is calibrated and in good working order.
- Understand how the instrument will respond to the materials being measured.
- Test the atmosphere when approaching the spill (especially if in a vessel, tank manway, or low-lying area).
- Use equipment and tools that are intrinsically safe/explosion-proof.
- Observe confined space procedures if entering a confined space.

In potentially flammable atmospheres, restrict the use of instruments that are not intrinsically safe. These include:

- Open lights
- Flames
- Internal combustion engines
- Non-approved radio transmission devices
- Cellular phones

All hydrocarbons have a concentration range in which they are combustible. When either too little or too much hydrocarbon is present in air, the mixture will not burn. Also, in confined spaces, the oxygen level must be 10% or higher for combustion to occur. When evaluating the risk of fire or explosion, the key measurement is the lower explosive limit (LEL). The LEL is the lowest concentration of a vapor for a given material that will support combustion. Below this concentration, the mixture is too lean (dilute) and cannot support combustion. Detectors are used to determine whether or not a mixture is combustible. However, most combustible gas detectors (LEL meters) will not work properly in an area that has an oxygen concentration below 14–16%. Therefore, to test confined spaces or inerted containers for hydrocarbon level, the oxygen content must be measured first by properly protected personnel.

If LEL meter reading is:	Then:
0% (zero) to less than 10% of LEL	Hot work (i.e., with potential ignition sources) is allowed
Greater than 10% and less than 25% of LEL	Proceed with care, especially where there is poor air movement or circulation
Greater than 25% of LEL	Leave the area quickly and carefully

LEL meters do not detect toxic hazards. A reading of just one-tenth of a low LEL of 1.0% could still be toxic (1000 ppm of hydrocarbons can be dangerous to life and health)! Although flammability testing should be the first level of assessment, the decision to enter or work in an area should not be based solely on flammability.

2.2.2 *Hazardous Atmospheres/Hazardous Chemicals*

Crude oil contains substances that can cause acute as well as chronic health effects. Acute effects are more immediately evident and typically result from relatively short duration, high exposure conditions. Examples of acute effects include eye or skin irritation or even death under extreme exposure conditions. Most of the acutely toxic substances are highly volatile and are present in their highest concentrations soon after the spill. Chronic effects may develop some time after the initial exposure and are often associated with longer duration, lower concentration exposures. Chronic effects include certain diseases such as cancer.

Health advisors (e.g., Industrial Hygienists) are key in assessing whether or not an area is hazardous, especially early in a spill. Rely on them to determine proper protective measures for responders likely to be in the exposure zone. Such assessments should be based on the most likely level of exposure, taking into account the expected elevation of work activity, for example, boat deck level as opposed to water surface.

Health risk from inhalation of harmful vapors is lower for weathered crude than it is for fresh crude. In most cases, crude oil that has weathered for more than 6 hours is likely to have a much lower percentage of volatile compounds mainly due to evaporation. This could take longer in colder weather (see Section 15). Keep in mind that some tasks may agitate crude oil and increase the release of vapors.

The primary health risks associated with fresh crude are related to the inhalation of:

- Hydrogen sulfide (H_2S)
- Hydrocarbon vapors
- Benzene

Workers exposed to some of these substances through inhalation or skin contact may experience symptoms such as:

- Eye, nose, throat, or respiratory irritation
- Skin rashes or reddening
- Other adverse effects

Except for ingestion or aspiration of oil aerosols, the health concerns with weathered crude relate to skin exposure. Skin contact with hydrocarbons, as well as other potentially toxic substances, should be avoided through the use of proper protective equipment. Prolonged or repeated skin contact may result in dermatitis as well as increased body uptake of some crude oil components. Increased sensitivity to oils can also occur as a result of repeated exposures.

The nature of the hazards from refined products depends on their chemical composition. Typically, two categories of products are distinguished:

- Light-end refined products do not have significant H_2S concentrations, but contain a higher percentage of volatile aromatic (e.g., benzene) and oxygenated compounds.
- Heavy-end products and intermediates may contain H_2S, less volatile compounds, and a higher percentage of low-volatility polycyclic (or polynuclear) aromatic hydrocarbons (PAHs).

Health hazard assessment information should be obtained from the supporting industrial hygiene/safety and/or medical personnel. These individuals have been trained in the use of the specialized testing equipment necessary to conduct exposure assessments.

Typical health hazards for workers involved in crude oil or refined hydrocarbon spill response and First Responder Guidance are summarized in Tables 2-3 and 2-4. Selected items, including potential health issues seen after the initial response, are discussed in more detail following the tables (sections 2.2.2.1 through 2.2.2.8).

Exposure criteria are American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Values (TLVs). These limit values are current as of 2014. Where local laws or company limit values are more stringent, those limits should be observed. In addition, ExxonMobil has established its own Occupational Exposure Limits for benzene, hydrogen sulfide, and gasoline (Table 2-2).

Table 2-2 ExxonMobil's Occupational Exposure Limits for Benzene, Hydrogen Sulfide, and Gasoline

Substance of Concern	8-hr Exposure Criteria (ppm)	15-minute Exposure Criteria (ppm)
Benzene	0.5	1
Hydrogen Sulfide (H2S)	5	10
Gasoline	100	200

Table 2-3 Health and Safety Information for Selected Substances[1]

Substance of Concern	8-Hour Exposure Criteria	15-Minute Exposure Criteria	Odor Threshold	Air-Purifying 1/2 Facepiece Respirator Criteria	Cartridge or Filter Required	Air-Purifying Full Facepiece Respirator Criteria	Supplied-Air Respirator Criteria Positive Pressure Mode	Protective Clothing Selection	Flammability Range (% by volume)
Hydrogen sulfide	1 ppm	5 ppm	0.005 – 0.013 ppm (2)	Not suitable	N/A	Not suitable	≥5 ppm for more than 15 minutes	— —	4.3 – 44.0
Hydrocarbon vapors (crude oil) (3)	100 ppm	200 ppm	0.11 ppm (4)	≥100 ppm <1,000 ppm	Organic vapor	≥1,000 ppm <5,000 ppm	≥5,000 ppm	Nitrile, Viton, Barricade™ Responder™ Eye goggles if irritation	Varies depending on oil
Gasoline	300 ppm	500 ppm	0.3 ppm	≥100 ppm <1,000 ppm	Organic vapor	≥1,000 ppm <5,000 ppm	≥5,000 ppm	Nitrile, Viton, Barricade™ Responder™ Eye goggles if irritation	1.3 – 7.1
Middle distillates	200 mg/m^3	<1,000 mg/m^3	N/A	200 – 2,000 mg/m^3	Organic vapor	≥2,000 mg/m^3 <10,000 mg/m^3	≥10,000 mg/m^3	Nitrile, Viton, Barricade™ Responder™ Eye goggles if irritation	0.6 –6.5
Benzene	0.5 ppm	2.5 ppm	2.0–5.0 ppm (5)	≥0.5 ppm <5 ppm	Organic vapor	≥5 ppm <25 ppm	≥25 ppm	Viton CPF™, Responder™ Tychem 10,000™	1.3–7.9
Oxygen-deficient atmospheres (confined spaces)	Acceptable concentrations are from 19.5% to 23%		N/A	Not suitable below 19.5%	Not suitable below 19.5%	Not suitable below 19.5%	<19.5%	N/A	N/A

(1) Some companies choose to adopt lower exposure levels consistent with their interpretation of the toxicological data. Always use what your company has adopted as an exposure limit unless local regulations are more stringent.

(2) The "rotten egg" odor of H_2S should not be relied on to determine its presence or absence because elevated concentrations of H_2S can numb the olfactory nerves.

(3) The vapors are hydrocarbons in the gasoline/napththa range. The initial components that evaporate from crude oil are roughly equivalent to gasoline vapors. This number is based on the ExxonMobil Occupational Exposure Limit for gasoline, which is 100 ppm TWA and 200 ppm STEL. For spills of heavy hyrdocarbons or middle distillate products, the guidance values are more severe (see sections 2.2.2.5 and 2.2.2.7 respectively

(4) May vary significantly between crude types and ambient conditions.

(5) Reported threshold of sensory irritation to upper respiratory system.

Table 2-4 provides a step-by-step approach for establishing the overall safety of a work area.

Table 2-4 Health Monitoring Guidance for First Responders (Use with Table 2-3)

Step	Action
1. Establish LEL Level (a,b) • <10% LEL • 10–25% LEL • >25% LEL	 • Go to Step 2 • Go to Step 2 but carry out operations with care • Do not proceed to Step 2 until <25% LEL
2. Establish H_2S Level (c,d) • <1 ppm • >1 ppm	 • Go to Step 3 • See Table 2-3 for proper protection then proceed to Step 3
3. Establish Hydrocarbon Vapor Level (e,f) • <100 ppm (<27 ppm for jet fuel or kerosene and <11 ppm for diesel) • >100 ppm (>27 ppm for jet fuel or kerosene and >11 ppm for diesel)	 • Go to Step 4 • See Table 2-3 for proper respiratory and protective clothing protection and then proceed to Step 4
4. **Establish Benzene Level (g,h)** • <0.5 ppm • >0.5 ppm	 • Proceed with operations • See Table 2-3 for proper respiratory and protective clothing protection and then allow workers into the area

a) Monitor in the worst-case spark zone (i.e., at the elevation with the highest potential exposure) with a calibrated instrument. Continue to monitor as conditions change, such as a drop in wind velocity.

Note: If monitoring in a confined space, monitor for oxygen first (see section 2.2.1)

b) Numerous LEL monitoring devices are available and most refineries have them. Some of the devices also measure oxygen and hydrocarbon level. They all require calibration prior to use.

c) Monitor in the worst-case breathing zone using a calibrated instrument. Continue to monitor as conditions or work tasks change. Contact the Industrial Hygiene rep to determine safe levels.

d) A wide range of H_2S monitors are available. Colorimetric tubes also work.

e) Exxon/Mobil OEL for gasoline is 100 ppm TWA, 200 ppm STEL. The TLV for gasoline is less stringent (300 ppm TWA, 500 ppm STEL.) Refer to Table 2-2.

f) Photo-ionization detectors (PIDs) are commonly used to measure Total Hydrocarbons. Calibrate with 100 ppm isobutylene standard gas.

g) Only a limited number of direct reading techniques can selectively measure <0.5 ppm of benzene in air. Two techniques that have been used are (1) compound specific PIDs (see above) and, (2) colorimetric samplers. Benzene PIDs PIDs with scrubber tube measure the current associated with ionization of benzene. Colorimetric samplers chemically react the benzene to form a color whose intensity can be correlated to concentration.

h) Since benzene is a chronic hazard, the 8-hour criterion of 0.5 ppm can be met with limited exposure times at higher concentrations as long as the 15-minute criterion of 2.5 ppm is not exceeded.

2.2.2.1 Benzene

Benzene is a volatile component of crude oil that is a human carcinogen. Therefore, exposure to benzene should be kept within applicable exposure limits, as defined in Tables 2-2, 2-3, and 2-4.

2.2.2.2 2-Butoxyethanol

Some dispersants and remediation chemicals contain hydrocarbons such as 2-butoxyethanol (2BE) which can enter the body through the skin as well as through inhalation. This can result in temporary effects on internal organs, such as kidneys. Care should be exercised in handling these products.

Follow the handling guidelines provided on the MSDS, especially:

- Avoid skin contact when using products containing 2BE. If contact occurs, wash with water immediately.
- Avoid spraying these products in a manner that will produce large amounts of overspray or vapor exposure to workers.
- Wear proper protective equipment:
  - Respirators (Monitor using charcoal tubes or charcoal badges)
    - 20–200 ppm — Half facepiece respirator with organic vapor cartridges
    - 200–2000 ppm — Full facepiece respirator with organic vapor cartridges
    - >2000 ppm — SCBA: Self-Contained Breathing Apparatus
  - Gloves and Clothing
    - Butyl, Neoprene, nitrile, Viton®, Saranex™

2.2.2.3 Carbon Monoxide

Burning crude oils or refined products produces carbon monoxide and other combustion products that must be assessed on a case-by-case basis. Do not place combustion equipment (generators, vehicles, direct-fire space heaters, etc.) that can generate carbon monoxide (CO) next to living areas and offices. Contact on-site industrial health and safety personnel for guidance.

The TLV for CO is 25 ppm as an 8-hour time weighted average. Since it has poor warning properties, SCBAs are required above this concentration.

Warning signs of carbon monoxide exposure are headache, dizziness and nausea. Higher levels of exposure cause reddening of the skin, weakness, mental confusion, and hallucinations.

2.2.2.4 *Gasoline*

Most of the vapors given off by gasoline are aliphatic and low molecular weight in nature. Volatilization is very rapid so dissipation will occur very quickly. Gasoline and other fuels with a low flash point present added safety concerns when spilled. Containment and skimming are **not recommended** due to potential fire or explosion hazard. Follow control recommendations listed in Tables 2-2, 2-3, and 2-4.

2.2.2.5 *Heavy Hydrocarbon Products*

Heavy hydrocarbon products are higher viscosity products such as heavy crude oils, bunker fuels, residual fuels, numbers 4–6 fuel oils, and gas oil. These materials can contain PAHs. PAHs are low volatility, high molecular weight hydrocarbons that with repeated contact can potentially cause skin and lung cancer. The TLV used by industry for these compounds is 0.2 mg/m^3 (as benzene soluble aerosol) and is listed under Coal Tar Pitch Volatiles. Primary protection against these materials is prevention of skin contact through the use of Personal Protective Equipment (PPE). Although risk from inhalation of volatiles is minimal (due to low vapor pressure), inhalation of aerosol mists (e.g., from steam or high pressure water clean-up techniques) should be avoided.

Primary protection against PAHs is the prevention of skin contact. Protective clothing should be worn to prevent any incidental skin contact. Materials that will adequately protect against PAHs include nitrile, Viton®, Barricade™, Teflon™, 4H™, CPF3™, Responder™, and Tychem 10.000™. If contact occurs, remove any contaminated clothing and wash thoroughly with soap and water.

The sensory threshold for these materials is about 1 mg/m^3 based on upper respiratory tract irritation. (The mg/m^3 designation is used here, not ppm, because PAHs are solid particulates, not volatile gases.) Half facepiece respirators with high efficiency filter and organic vapor cartridge should be worn in the 0.2–2.0 mg/m^3 concentration range. Full facepiece respirators with high efficiency filter and organic vapor cartridge should be worn in the 2.0–10.0 mg/m^3 concentration range, and SCBAs would be needed when there is greater than 10 mg/m^3. Some companies believe that a more stringent value is necessary for proper protection (e.g., 0.1 mg/m^3). A 0.1 mg/m^3 guide would lower the above thresholds by a factor of 2.

2.2.2.6 Hydrogen Sulfide (H_2S)

Hydrogen sulfide, a byproduct of decomposing organic material, is a compound contained in some crude oils and refined intermediate products. Exposure to elevated concentrations of H_2S can be fatal. The primary exposure route is inhalation. Measurement of ambient H_2S concentrations should be performed when approaching a spill area. Remember these guidelines:

- H_2S is heavier than air and may accumulate in low storage areas, pump rooms, or confined spaces.
- H_2S has the distinct odor of rotten eggs that can be detected at concentrations as low as 0.006 ppm; however, the sense of smell should not be used in place of a detection device because H_2S can deaden the sense of smell at high concentrations.
- At low concentrations (1 ppm to 150 ppm), H_2S is irritating to the eyes, nose and respiratory system.
- At elevated concentrations (above 500 ppm), rapid paralysis of the respiratory system can occur.

Follow control recommendations in Tables 2-2, 2-3, and 2-4.

If H_2S is detected above 1 ppm, evacuate the area immediately until expert help and specialized equipment are available.

2.2.2.7 Middle Distillate Products

Petroleum materials boiling between 145 and 450 degrees C are called middle distillates. They include kerosenes, diesel fuels, jet fuels, and heating oil. These products are of greater concern in the aerosol form than in the vapor state so the TLV levels are considerably lower than for crude and gasoline. Repeated or intermittent dermal exposure to these materials can lead to dermal irritation and may be associated with an increased risk of skin cancer.

Primary protection against these materials is through the proper use of PPE. Protective clothing selection would be similar to that recommended in Table 2-3. If contact occurs, remove any contaminated clothing and wash thoroughly with soap and water.

The current TLV for kerosene is 200 mg/m^3 (about 27 ppm) and for diesel is 100 mg/m^3 (about 11 ppm). For kerosene, half facepiece respirators with organic vapor cartridges should be worn in the 27–270 ppm concentration range. Full facepiece respirators with organic vapor cartridges should be worn in the 270–1350 ppm concentration range, and SCBAs would be needed when there is more than 1350 ppm.

For diesel, half facepiece respirators with organic vapor cartridges should be worn in the 11–110 ppm concentration range. Full facepiece respirators with organic vapor cartridges should be worn in the 110–550 ppm concentration range, and SCBAs would be needed at over 550 ppm.

2.2.2.8 Oxygen

Oxygen concentrations below 19.5% (at sea level) are viewed as **Immediately Dangerous to Life and Health (IDLH)** environments. Low oxygen atmospheres are possible in enclosed spaces. Therefore, strict entry controls and permits as well as proper air supply respiratory protection are required. SCBAs are required in oxygen atmospheres less than 19.5%.

Effects of oxygen abnormalities are listed below:

Oxygen Levels	Effects
Approximately 6%	Difficult breathing with death in minutes
Approximately 17%	Impaired judgment and headaches
Greater than 23%	Raises the danger of combustibility

A health professional should be consulted for work performed at higher elevations to assess any potential health effects due to the reduced concentration of oxygen.

2.2.2.9 Overall Guidance

It is essential that responders understand the potential atmospheric hazards existing in the environment that they are expected to work in. Generally, health and safety experts will be onsite to characterize the quality of the ambient air prior to allowing response workers into a suspect area. However, in the event that testing is delayed, the following general guidelines may be useful:

- Responders at a spill where oil is still fresh should wait for testing before proceeding or wear respiratory protection.
- Responders arriving 6 hours or more after a spill in open water with good air circulation (which is usually the case) can probably proceed without concern for the issues discussed above unless the spill is quite large (over 10,000 bbls). For contained spills or spills on land, the issues are more relevant.
- Always avoid prolonged skin contact with hydrocarbons.
- Always approach the spill from the upwind direction.

2.2.3 Heat and Cold

Climatic conditions pose additional risks to cleanup workers. One of the primary responsibilities of each person is to monitor his/her "buddy" for symptoms of heat or cold stress. All workers should be trained to recognize and guard against the symptoms and provide the appropriate first aid. Both conditions are described on the following pages.

2.2.3.1 Heat Stress (Hyperthermia)

Heat stress is caused by the inability of the body to dissipate excess heat generated from physical exertion, temperature and humidity, or the wearing of protective clothing and equipment. Responding to spill emergencies increases the risk for heat stress. The use of protective equipment (especially in tropical areas) compounds the problem by increasing the heat load, preventing adequate heat dissipation and decreasing evaporative cooling. It is important to prevent heat-induced illnesses and injuries and recognize early symptoms of heat stress.

More serious heat-induced illnesses or injuries are often caused by ignoring early symptoms.

The four "stages" of heat stress and their relevant first aid recommendations are presented in Table 2-5.

2.2.3.2 Cold Stress (Hypothermia)

Cold stress is caused by a rapid loss of heat from the body that can cause localized minor to severe injuries, as well as system dysfunction. The most prevalent cold stress injuries involve the extremities: typically the hands, ears, nose and/or feet.

All workers in cold climates must be trained to recognize and guard against the symptoms of cold stress and provide proper first aid. The stages of cold stress and their relevant first aid recommendations are outlined in Table 2-6.

Some form of immersion protection must be worn by personnel at risk of falling in water at temperatures below 68°F (20°C). Speed is essential when rescuing a person who has fallen overboard.

Table 2-5 Heat Stress Stages and Appropriate First Aid

Heat Stress Stage	Symptoms	Typical Causes	First Aid Recommendation
Heat Rash (prickly heat)	• Rash on the skin.	• Humid environment or wearing protective equipment that holds moisture next to the skin.	• Provide place for worker to thoroughly wash skin. • Offer rest periods in cool location. • Apply medicated powder.
Heat Cramps	• Muscle spasms in hands, feet, abdomen. • May also be accompanied by nausea/vomiting. • Person becomes quiet/stops work.	• Large electrolyte loss due to sweating which disrupts the electrolyte balance in the body.	• Offer fluids with proper balance of electrolytes, such as commercially available sports drinks. • Offer rest periods for routine fluid intake.
Heat Exhaustion	• Pale, clammy, moist skin. • Nausea/headache, dullness of response/work pace. • Person may become quiet, sit down, or faint.	• Excessive water loss, inadequate replacement. • Worker may not be acclimatized to work, equipment and/or climate.	• Relocate worker to cool place (shade). • Remove protective equipment (if appropriate). • Offer plenty of liquids with electrolytes. • Seek medical care/advice.
Heat Stroke	• Skin may be dry, reddish, and hot. • Person may faint or become disoriented. • Convulsions may occur with vomiting and rapid pulse rates.	• Temperature regulatory control has failed. • Body can no longer rid itself of excess heat.	• **Seek medical care immediately!** • Remove protective clothing. • Wet with cool water, cold beverage bottles. • If person is conscious, provide small but continuous amount of cool water/electrolytes. • Do not leave person unattended.

Table 2-6 Cold Stress Stages and Appropriate First Aid

Cold Stress Stage	Symptoms	First Aid Recommendation
Frost Nip	• Sudden whitening of the skin. • Skin is still flexible but firmer than normal. • Pain is typically experienced.	• Warm worker's affected body part slowly. • Keep worker warm until color and sensation of touch return to normal.
Superficial Frostbite	• Skin has "waxy" or white appearance. • Skin is not flexible on the surface. • Beneath the surface, tissue is still flexible. • Painful.	• Warm worker's affected body part slowly. • Provide warm shelter and offer warm fluids. • Seek medical follow-up.
Deep Frostbite	• Bodily tissue is cold, pale and solid.	• **Seek immediate medical care.** • Cover worker but **do not** try to bend or flex body part prior to medical care.
Hypothermia in Air (gradual loss of core temperature)	• Shivering. • Personality change. • Slow movement. • Person may become gradually quiet over several minutes. • Shivering may stop and person may be conscious but not coherent.	• **Seek immediate medical care.** • Perform CPR if necessary. • Gently remove wet clothing, cover with dry blankets or a sleeping bag (get in with victim to provide extra warmth). • If conscious, give "sips" of warm water or milk. • **Do not give alcohol.** • Never leave the victim alone.
Hypothermia Due to Immersion (rapid loss of core temperature)	• Even a short immersion unprotected in cold water can cause rapid hypothermia. • Death could occur in less than 30 minutes. • Above symptoms occur rapidly.	

2.2.4 Site Conditions

Historically, most injuries during a spill response have been from slips, trips, and falls. These can be minimized through the concept of **Present Moment Thinking:**

- Be aware at all times.
- Think of what you are doing, not what you are going to do next.
- Guard against daydreaming.

2.2.5 Miscellaneous Hazards

2.2.5.1 Noise

If you need to shout to communicate within 2–3 feet (0.6–1 meters) of each other, sound pressure levels (noise) are assumed to be above the threshold for wearing hearing protection (85 decibels). Wear hearing protection when continuously exposed to noise levels above 85 decibels.

2.2.5.2 Other Hazards

Also be aware of hazards from:

- Solar radiation
- Large mammals (e.g., bears)
- Venomous snakes
- Other domestic or wild animals
- Poisonous plants (e.g., poison ivy)
- Insect bites and stings
- Off-road vehicle accidents (e.g., roll-over)
- Uneven terrain
- Dangerous weather (lightning, hail, strong winds)
- Blood or other body fluids (use a mask or barrier device for CPR)

2.3 Protective Equipment

Protective equipment suitable for the exposures and risks should be used by all spill response personnel. Protective equipment will typically consist of:

- Hard hats
- Gloves
- Coveralls
- Boots
- Safety glasses
- Eye goggles
- Respirators
- Hearing protection
- Insect repellants and mosquito netting in tropical areas

The type of protective equipment selected is determined by the material that has been spilled, the tasks to be performed, and environmental factors.

It is important to have established policies on the protective equipment to be used and to ensure that these policies are followed, especially in a large operation.

2.3.1 Protective Clothing

The materials for protective clothing should be selected for oil and refined product spills based on the following factors:

2.3.1.1 Splash Potential Only

Workers exposed only to occasional splash, vapor or mist

Rain suits along with industrial rubber boots typically give adequate body protection against splashes. Gloves selected for a specific hazardous material may also be required depending on the work being performed.

2.3.1.2 Hydrocarbon Immersion Potential

Worker has potential for repeated immersion of hands, feet, or body parts

Workers who will have body parts potentially exposed to hydrocarbon contamination should use permeation-resistant protective equipment that affords the best level of protection for the specific hazardous material and/or mixture.

All materials are eventually permeable to a contaminant. Therefore, always limit direct contaminant contact. Workers must be trained to properly don, seal, and remove equipment, and to guard against heat or cold stress while working in this equipment.

Hard hats and safety shoes should be used for all field work. Non-slip soles should be provided for marine and wet work areas.

2.3.2 Respiratory Protection

The risk of inhaling oil vapors or other hazardous compounds is typically highest immediately after the spill but can continue throughout the cleanup. Additional inhalation exposures could occur during in-situ burning and during the use of chemical countermeasures used to combat the spill such as dispersants, beach cleaners, or chemicals used to promote microbial degradation of oil. Respiratory protection can be provided by an air-purifying respirator or a self-contained breathing apparatus (SCBA)/air-line system. Responders carrying out typical daily tasks would not normally be expected to wear SCBA gear. The following points should be considered when selecting air-purifying respirators:

- Consult the responsible safety or industrial hygiene personnel before issuing or using respirators.
- Employees with facial hair will not be assigned work requiring respiratory protection. **Respirator users must be clean-shaven.**
- All workers must have training and fit testing before using respirators.
- Only certified respirators will be used.
- Air-purifying respirators do not protect against H_2S, carbon monoxide, or any other material for which they are not designed.
- Filters or cartridges remove contaminants from the air and must be properly selected for the anticipated hazard. They will not protect in oxygen-deficient environments.
- Cartridges (organic vapor/acid) have a limited service life. When odor is detected, replace the cartridge.
- Cartridges and filters can be combined to afford protection against a variety of vapors, particulates, and gases.
- Cartridges from one brand cannot be safely used with another brand of respirator.
- Depending on the concentration and potential for irritation, either half face piece or full facepiece respirators can be worn (see Table 2-3).

- Workers wearing glasses should use a spectacle kit for full-face piece respirators. Lenses can be ground locally to fit in a frame provided by the respirator manufacturer. Regular eyeglasses cannot be worn in respirators. Contact lenses should never be worn in areas where irritating vapors could be present.

Supplied-air respirators are used when air-purifying devices do not provide enough protection. They are required for confined space entry (see below), environments that are **Immediately Dangerous to Life and Health (IDLH)** and other high exposure risk areas. Environments that are greater than 3000 ppm TPH or less than 19.5 % oxygen (at sea level) are IDLH.

Workers must have hands-on training before using supplied-air respirators in the field. There are two types of supplied-air respirators:

- **Self-contained**: Good for short period (1-hour duration or less) emergency/rescue only. These should have a full facepiece and a pressure demand regulator.
- **Air-line**: Good for long-duration work. Should have emergency bottles to allow enough time for safe exit if air supply is lost. (NOTE: 300 feet or 100 meters of air line is the maximum allowable length from the air source.)

All respirators must be cleaned, decontaminated, disinfected, and air-dried after use. They should be inspected and repaired before they are put back into service. Qualified personnel must perform servicing.

2.3.3 Confined Space Entry

Spill response efforts sometimes require workers to enter confined spaces such as tanks and cargo holds that have limited access and poor ventilation. On-site industrial hygiene and safety professionals should establish the exact confined space entry procedures and the required protective equipment. Conditions within these confined spaces can change quickly. Therefore, the atmosphere must be tested (O_2 → LEL → H_2S → TPH → Benzene) before entry and tested continuously throughout the work. Portable equipment with preset audible and visual alarms should be used.

2.4 Personal Health

Workers have the responsibility to maintain their personal health

- Complete periodic medical evaluation.
- Keep an ample supply of personal medications and be sure to pack them.

- Carry a spare set of corrective lenses.
- Keep immunizations up-to-date.
- Keep anti-malaria medication on hand (as applicable) for up to ten days of protection.
- Notify your management if there is any change in health status that would preclude working in areas with substandard medical care.

2.5 Transportation Safety

2.5.1 Small Boat Safety Rules

Small boats are used extensively during crude oil or refined product spills on large bodies of open water. Some basic safety rules are as follows:

- Select boats that are appropriate for the conditions at hand, i.e., do not use calm water, shallow draft boats offshore.
- There should be sufficient personal flotation devices for all persons aboard and these must be properly worn at all times when persons engage in the following activities:
  - Working near the deck edge.
  - Boarding and disembarking.

Personal flotation devices are only effective when they are secured.

- Decks are slippery: **Be careful**!
- Do not overload the vessel.
- When traveling in a boat:
  - Obey speed limits at all times especially in and out of inlets and ports.
  - Yield right of way as required by navigation rules.
  - Have a proper first aid kit, emergency signal kit, and communications equipment, navigation equipment, running lights, and warning horns on board.
  - Avoid setting out in bad weather or rough seas unless absolutely necessary and deemed safe to do so.
  - Always inform someone of your trip destination, course, radio frequency, planned activities, and estimated time of arrival/return.
  - No smoking or alcohol use.
- Dress warmly; in winter, temperatures away from the coastline usually decrease and the wind chill can be significant.

- Stay out of the water unless absolutely necessary; remember, hypothermia can occur in minutes.

2.5.2 Aircraft Safety Rules

Prior to flying, the pilot will give passengers a pre-flight safety briefing (see Chapter 16 for more details). However, some basic safety rules are as follows:

- The pilot is in charge of the aircraft and passengers during all phases of flight and in emergency situations.
- When approaching or leaving the aircraft:
  - Approach after the pilot has signaled.
  - Always approach or leave at a 90° angle to the aircraft nose and in view of the pilot.
  - Never walk near or under the tail rotor of a helicopter or near the propeller of an airplane.
  - Always approach or leave a helicopter in a crouched position unless it fully stopped.
  - Do not disembark any aircraft until instructed by the pilot.
- Passengers and pilots must wear:
  - Seat belts at all times — from takeoff until after the aircraft has landed.
  - Hearing protection on all helicopter flights.
  - Inflatable life jackets during over-water helicopter flights.
- Smoking by passengers and pilot is prohibited on or near the aircraft.
- Persons under the influence of drugs or alcohol must not be allowed to board.
- Learn the location of and know how to operate emergency exits and emergency equipment such as life rafts, emergency equipment kits, and fire extinguishers.
- Do not inflate the life jacket or the life raft inside any aircraft.

2.6 Decontamination

Personnel involved in any oil spill cleanup operation can get very dirty. It is important to keep oily gear and dirty personnel out of living quarters in order to maintain satisfactory conditions. One way to do this is to set up personnel decontamination facilities for workers coming off the job. This includes facilities for cleaning and storing soiled personal protective equipment followed by washing, showers, and lockers, as appropriate. A typical design of a decontamination facility can be set up as follows in a serial arrangement:

entrance → dirty side → showers → clean side → exit

3 Logistics and Communications

3

3.1 Introduction

This section discusses the logistics required to support workers who participate in response operations. It also includes some of the communications needs to effectively manage a response as the conditions of an oil spill change. The mobilization of personnel, supplies, and cleanup equipment into the spill area is not discussed.

3

3.2 Logistics

A rapid response is essential for effective spill cleanup. Effective logistics ensure the expedient and efficient mobilization of resources and sustained resource availability throughout the response effort. Some key logistics elements are described below:

Logistics planning usually includes the following key points:

Table 3-1 Key Logistics Elements

Resources	Support	Services
• Contracts for goods and services • Procurement • Shipping/receiving • Warehouse/staging • Inventory management • Equipment tracking	• Transportation • Provisioning • Permits • Waste management • Assembly, fabrication and maintenance • Demobilization	• Decontamination • Security • Facilities • Administrative services

- Prioritize objectives and allocate resources accordingly.
- Allocate equipment appropriate to the job:
  - Use fixed-wing aircraft for heavy loads and extended flights.
  - Use locally available aircraft when possible.
  - Locate fuel depots near work areas.
- Acquire marine charts, tide tables, maps, weather forecasts, aviation charts (especially near controlled airspace).
- Obtain procurement documents: purchase orders, contracts, and rental agreements.
- Acquire necessary permits if required:
  - Hazardous goods transport
  - Industrial waste disposal
  - In-situ burning

- Chemical applications (e.g., dispersants, shoreline cleaners, etc.)
- Vessel docking
- Aircraft
- Land or property access
- Approvals for various activities (e.g., washing booms in place)

- Implement financial controls:
  - Do not make long-term agreements.
  - Document all transactions and agreements.
  - Appoint expenditure officers; limit signing authority.
  - Control inventory of equipment and supplies.
  - Track purchase orders, invoices, contracts, and labor charges.

3.2.1 Resources

Various response team sections should work together to identify the resources, support and services required for a response operation. A detailed Material Take Off (MTO) list can then be compiled to summarize the findings. Sample MTO lists specific to each area of spill response are provided in:

- Section 4 (Tracking and Surveillance)
- Section 5 (Boom)
- Section 6 (Shoreline Protection)
- Section 7 (Dispersants)
- Section 8 (In-Situ Burning)
- Section 9 (Skimmers)
- Section 11 (Transfer Systems)
- Section 12 (Shoreline Treatment)
- Section 13 (Oiled Wildlife Response)
- Section 14 (Waste Management)

These MTO lists are not intended to be all-inclusive but instead provide an idea of the scope and equipment typically required for each type of spill response operation.

Planning all spill cleanup phases from start to finish not only saves time and effort but also can allow operations to continue without major interruptions.

3.2.1.1 Contracts

Contractual arrangements should be made as soon as possible for outside goods and services identified on the MTO.

3.2.1.2 Procurement

Procuring goods and services identified on the MTO should begin as soon as possible. All goods and services ordered should have an end-use designation based on field requirements. This will minimize over- or under-ordering.

3.2.1.3 Shipping/Receiving

In the early stages of a response, a functional system for the receipt of equipment and supplies is essential. Incoming freight must be efficiently managed to ensure timely delivery to the appropriate field destination. The receiving area should be the point at which inventory control and material accounting are initiated. Shipping procedures also need to be established. Examples of items that may be shipped from a spill location include samples collected for laboratory analysis, equipment needing repair, and materials that need to be returned.

Customs clearance procedures specific to the country should be established prior to receiving equipment and supplies or shipping materials out of the region. ***Customs clearance can be a potential issue if not addressed early in the response.***

3.2.1.4 Warehouse/Staging

Staging areas should be identified as early as possible in the response so that when equipment is received, it can be sent to the appropriate location. Staging areas are temporary. They are located for the convenience of the response and moved or decommissioned as appropriate. Warehouses may also need to be established to securely store reserve supplies, spare parts, and equipment, plus function as a shipping and receiving facility.

3.2.1.5 Inventory Management

An inventory management system needs to be established as soon as possible. The system should include all aspects of inventory control such as procurement, receipt, issue, use, and final disposition.

3.2.1.6 Equipment Tracking

The status of all resources assigned to response should be tracked and reported daily to the Operations Manager or his/her designee. The status should include in-transit, standby, and activated or deployed resources from every source, including those from emergency response organizations and agencies.

3.2.2 Support

3.2.2.1 Transportation

Transportation involves the movement of personnel and material to and throughout the field. It includes marine, land, and air operations. Providing adequate transportation is a priority, especially during the early stages of response.

- *Marine Transportation*
  - Vessels of opportunity (e.g., tugs, barges, workboats, fishing boats) for boom tending, shuttle service, security, supplies delivery, storage, and waste/debris collection
  - Landing craft and skiffs for shoreline treatment and cleanup
  - Barges and ships for worker accommodations/berthing
  - Dedicated spill response vessels and barges

In U.S. waters, waivers may be available from the U.S. Coast Guard for the short-term emergency use of vessels that do not have a Certificate of Inspection.

Check local regulations and certification requirements when operating outside U.S. waters.

- *Land Transportation*
  - Buses, cars, light trucks, and all-terrain vehicles
  - Heavy-haul vehicles (e.g., dump trucks, flatbeds, and tractor trailers)
- *Air Transportation*
  - Fixed-wing aircraft, including float planes, for heavy cargo and extended flights; also for surveillance and passenger transport
  - Helicopters, both single and double rotor

3.2.2.2 Provisioning

Provisioning can be divided into two categories: Field (offshore) Provisioning and Onshore Provisioning.

- *Field (Offshore) Provisioning*
  - Personnel assigned to the field will require various levels of provisioning, including fuel, food, housing, water, supplies, and sanitation facilities.
- *Onshore Provisioning*
  - Response personnel stationed onshore will require food, shelter, supplies, and sanitation facilities. Local commercial establishments

may be available for some workers, but depending on the size of the response effort, temporary housing and canteen facilities may need to be brought into the area.

- To facilitate planning, provisioning requirements should be determined from Operations Section (Figure 1-1) before personnel are dispatched to field locations.

3.2.2.3 Permits

Various permits may be required, including for the following activities:

- Hazardous goods transport
- Industrial waste disposal
- In-situ burning
- Chemical applications (e.g., dispersants, shoreline cleaners, etc.)
- Decanting of separated water
- Vessel docking
- Aircraft landing
- Land or property access
- Activities involving oiled equipment or oily waste management (e.g., washing booms in place, oily waste decanting)

3.2.2.4 Waste Management

Both short- and long-term waste management plans should be developed during the early stages of a spill response operation. The plans should consider mechanisms for waste collection, containerization, storage, transportation, disposal, and tracking.

3.2.2.5 Assembly, Fabrication, and Maintenance

Most equipment will require some level of assembly and testing to ensure its readiness for the field. These activities may include attaching hoses and fittings, installing batteries, or matching power supplies/packs to equipment (e.g., skimmers). Other equipment and/or facilities may need to be fabricated on site. This may require the expertise of mechanics, technicians, and various craftsmen. Systems should be in place for both preventative and remedial maintenance of response equipment. Maintenance activities may be carried out at the work location or at a pre-established central maintenance area. Fuel, lubricating oil, hydraulic oil, and other fluids will be required to keep vessels, aircraft, and vehicles operational.

3.2.2.6 Demobilization

Demobilization can occur very early in the response, and continue throughout as operational requirements change. Demobilization plans should be prepared for vessels, equipment, personnel, contractors, and facilities.

3.2.2.7 Decontamination

Decontamination capability must be provided in all responses. Plans should be prepared early in the response to address personnel, vessels, and equipment. Only approved cleaning chemicals should be used.

- *Personnel Decontamination*
  - Personnel decontamination will be required throughout the response effort. Personnel decontamination units can be fabricated on site or commercial modular units may be leased or purchased.
- *Vessel Decontamination*
  - Boats will accumulate oil on their hulls at and near the waterline. Soiled boats should not be brought into uncontaminated harbors without first being cleaned.
  - Boat hulls may be manually washed from a low-freeboard pontoon float in a temporary slip constructed inside a protected, boomed-off area.
  - Small skimmers may be pressure-washed while being suspended over a wash pit.

If the location of the cleaning station does not have direct access to shore facilities, a barge may be needed to provide supplies, communications, shelter, and sanitary facilities.

- *Equipment Decontamination*
  - Equipment decontamination will be necessary before equipment is moved through or to uncontaminated areas. This is especially evident as contaminated boom is moved from containment to protection or storage, or when cleanup equipment is moved from one area to another. See Section 5.12 of this manual for more details on boom washing.

3.2.3 Services

3.2.3.1 Security

Security should be established early in the response to control access to restricted areas such as the Command Center, docks, offices, warehouses, and lay down yards. The security function should also control access to the spill site. It may be necessary to interface with local agencies and police departments to assist with access control and/or to coordinate on possible terrorist activity. The security function can also provide surveillance for wild animals and assist with accounting for personnel en route to and from the spill site.

3.2.3.2 Facilities

Facilities must be located and established to accommodate various needs for the spill response. Facilities include the Command Center, briefing rooms, lay down yards, storage facilities, housing, and offices. Facility maintenance such as trash collection, sanitation, parking, shuttle service, and catering must be considered.

3.2.3.3 Administration

Administrative services support the response by ensuring the availability and reliability of administrative equipment and services. Examples include office machines, computers, fax machines, copy machines, forms, mail, courier service, clerical support, record keeping, local transportation, parking, and media equipment.

A sign-in and sign-out procedure will help ensure that the whereabouts of all participants who are actively involved at a spill cleanup site are known. Similarly, spill response equipment and materials used for cleanup duty from warehouses, trailers, and other facilities also should be tracked.

3.3 Communications

Effective communication is critical to command and control. One of the first priorities of the Emergency Response Manager is to establish a communications network that will cover the geographical area and provide for communications among all parties involved in the response. The Communications Unit in the Logistics Section of an ICS structure is responsible for providing these services.

There is a need for voice, text, data network, and field radio communication capabilities during an incident. It may be necessary to acquire dedicated telephone lines and internet services, plus equipment from a local phone company or internet service provider to provide communications and connectivity for response teams. For spill response crews or vessel or aircraft crews, radio communications must also be established to coordinate operations.

Key considerations for establishing telephone and computer network access include:

- There can be a lead time before obtaining services for a field command center from telephone and network providers (e.g., DSL service).
- Mobile WiFi hotspots are effective devices for interim communications via laptop computers using remote VPN access.
- Hotels or similar facilities may have internet and telephone services and could serve as field command centers.
- Local service providers and radio shops can be sources of rental communications equipment.

Communications systems and their applications are summarized in Table 3-2. Ranges of UHF and VHF radio transmissions are summarized in Table 3-3.

Table 3-2 Telephone, Radio, Satellite, and Internet Communications Applications

Type	Use			Range
	Description	Voice	Data	
Cellular telephones	Mobile communications (Use where network is available. Some cell phones are capable of push-to-talk, Walkie-Talkie functionality. Texting may succeed when regular calling does not.)	✓	✓ (if network is suitable)	Within area served/many worldwide
VHF-FM marine (156-158 MHz)	Inter-vessel communications (Use marine channels 9, 10 and 16 in US waters; channels may vary elsewhere)	✓		Line of sight
VHF-AM aircraft (118-136 MHz)	Ground-to-air communications (Use 123.050 or 122.850.)	✓		Line of sight
UHF oil spill (454/459.000 MHz) (US only)	Company frequencies for field coordination (Use intrinsically safe radio in hazardous locations.)	✓		Line of sight
High frequency (HF) radio (2-20 MHz)	Single sideband (SSB) (Use offshore.)	✓		30+ miles (48+ km)
General Mobile Radio Services (GMRS) (462 and 467 MHz range	Ground– to –ground communications using small hand-held walkie-talkies. (Requires an FCC license in the US)	✓		2-3 miles
Inmarsat Satellite	Voice and facsimile (Use offshore or in remote locations where approved.)	✓	✓	Worldwide
Low Earth Orbit (LEO)	Good for communication in remote areas (e.g., Iridium, Globalstar)	✓	✓	Worldwide

Table 3-2 Telephone, Radio, Satellite, and Internet Communications Applications (continued)

Type	Use			Range
	Description	Voice	Data	
Geostationary satellite	Good for communication in remote areas (e.g., Inmarsat)	✓	✓	Worldwide; yet not guaranteed at high latitudes (e.g., >80°N)
Push-to-Talk	Cellular-based offering, which allows Walkie-Talkie type functionality on some cell phones	✓		Vendor-specific offerings limits availability
Voice Over Internet Protocol (VoIP)	Can make and receive calls using telephone numbers via a broadband internet connection	✓		Worldwide
Telephone, facsimile, and modem	Voice, computerized data, and facsimile (Transmission systems require time to implement.)	✓	✓	Not mobile

Key considerations in implementing a communications network include:

- Obtain appropriate government communications licenses.
- Ensure that communications specialists are accessible.
- Ensure that marine weather forecasts are accessible.
- Ensure that individuals and groups have access to frequencies of common interest and follow a frequency allocation plan established by the Communications Section (Figure 1-1).
- Use intrinsically-safe/explosion-proof radios in hazardous environments.
- Allocate a dedicated safety / calling channel
- Individual work crews should use separate frequencies if available.
- Place UHF repeater stations as high as possible.
- Repeaters should be visible from all points in the coverage area:
  - Maximum range using repeater stations is about 60 miles (100 km).
  - Higher frequency signals (UHF) are more attenuated by vegetation than are VHF signals; use VHF in wooded areas.

- The number of radio channels will increase over time during a major spill.
  - Consider communication security needs: VHF and UHF are open channels
  - Consider integrating an incident communications network with any Common Operating Picture which may contain pre-populated, in-field infrastructure information

Table 3-3 Range of UHF and VHF Radio Transmission Versus Antenna Altitude

Altitude		**Range**	
Feet	Meters	Miles	Kilometers
0	0	Up to 5	Up to 8
60	20	Up to 20	Up to 30

3.3.1 Common Operating Picture (COP)

More widespread use of Geographic Information Systems (GIS) and electronics by responders to share information has led to the development of a computer-based tool, a Common Operating Picture (COP). COPs use GIS architecture to store and display a variety of geospatial data that can include hundreds of data layers from different data sources (e.g., Responsible Party, agencies, states, institutes). A COP is typically operated from within an incident command post and provides access to real time information on response operational status. Core data themes include weather, infrastructure (e.g., hospitals), personnel tracking, assets (e.g., boom location), trajectories, imagery (e.g., overflight), and facility information. Data management, information acquisition, and vetting duties must be addressed to maintain and operate a COP.

There is a strong and growing interest in the development of COPs because they provide (1) near real time situational awareness, (2) access to the same information by various groups in a response, (3) aid for decision making, and (4) a communications tool for internal and external use. The benefits of COPs are most obvious for complex incidents and will require greater personnel support.

4 Surveillance and Tracking

4

4.1 Introduction

Surveillance and tracking operations are critical in planning spill countermeasure options. Surveillance and tracking approaches consider observed slick size, location, and predictions of slick behavior, which are based on understanding of the processes that control oil movement and removal from the water surface.

Oil spilled into the aquatic environment is subject to various physical and chemical processes that cause the oil to change (weather) and migrate. Some processes cause oil to be removed from the water surface, while others change its form on the surface. Important factors that influence the behavior and fate of spilled oil include:

- Physical and chemical characteristics, such as viscosity, specific gravity, volatility, and maximum water content
- The quantity of oil spilled
- The prevailing weather and sea state conditions

Figure 4-1 depicts these processes, which are further described in Table 4-1.

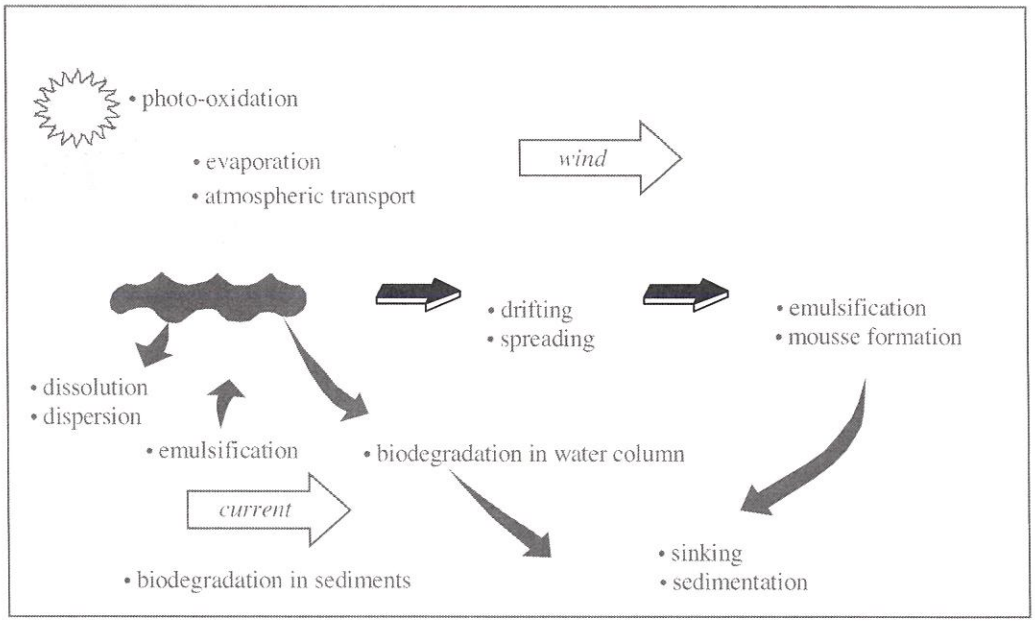

Figure 4-1 Processes Acting on Spilled Oil

Table 4-1 Processes Acting on Spilled Oil on Water

Process	Definition	Effects on Oil Spill Response
Drifting	Physical movement of surface oil from one location to another due to the combined effects of winds, and tides	Moves the location of oil slicks, which may affect response strategies
Spreading	Expansion of oil on the water surface due to gravity and advective spreading	Expands the areal extent of oil slicks as thickness diminishes
Evaporation	Physical-chemical process resulting in transfer of hydrocarbons from the water surface to the atmosphere	May result in the loss of 1/4 to 2/3 of the oil mass within a few hours or days and generally increases the viscosity of remaining spilled oil. Viscosity changes affect the selection of response options.
Emulsification and Mousse Formation	Formation of water in oil emulsions; can contain as much as 75–80% water	Increases density, viscosity, volume, and flash point of spilled oil; may affect selection of cleanup options
Dispersion	Transport of oil from the water surface into the water column due to wave action	Decreases volume of surface oil
Dissolution	Physical-chemical process resulting in dissolution of hydrocarbons in the water column	Small percentage of total amount; important because of potential toxicity
Sinking/ Sedimentation	Increase in density of oil due to weathering and interaction with suspended sediments or material of biological origin; deposition of material to the bed of the water body	Tracking and recovery of oil can be difficult and laborious, if not impossible; exposes organisms in water and possibly bed of the water body to oil
Atmospheric Transport	Transport of evaporated hydrocarbons in the atmosphere	May affect response decisions due to the concentration of hydrocarbons in the atmosphere; safety of personnel is the key issue
Biodegradation	Biological process altering or transforming petroleum hydrocarbons through microbial action	Slow process relative to other weathering mechanisms. Has limited effect on near-term oil fate or spill response
Photo-oxidation	Transformation of petroleum hydrocarbons through interaction with sunlight	Effects are negligible relative to other weathering mechanisms

4.2 Oil Properties and Fate

Regardless of their physical and chemical properties, all oils will weather once spilled. The rate of weathering depends on the conditions at the time of the spill and the nature of the spilled oil.

The following parameters are used to characterize oil properties:

4.2.1 API Gravity

A lower API Gravity indicates a higher specific gravity, and generally a higher viscosity. Physical removal methods are commonly used to recover very low API Gravity oils. High API Gravity usually implies low viscosity and a higher percentage of light ends. Oils with very high API Gravity are usually non-persistent and are more likely to evaporate or to be dispersed either naturally or using dispersants. High API Gravity oils may also be more readily burned, if circumstances allow. API Gravity can be calculated as follows:

$$\text{API Gravity} = (141.5/\text{Specific Gravity}) - 131.5$$

4.2.2 Flash Point

The flash point is the lowest temperature at which vapors above a volatile combustible substance ignite in air when exposed to a flame or spark. Fuels with a low flash point, such as gasoline, present additional safety concerns when spilled. Containment and skimming of low flash point oils are **not usually recommended** due to the fire or explosion hazard. Most response options can be considered for removing petroleum products with higher flash points, such as diesel, from the water surface. However, light oils, such as aviation gasoline, condensates, or Jet B, will naturally disperse and evaporate, quickly eliminating the need for response in non-sensitive areas.

4.2.3 Lower Explosion Limit

The lower explosion limit or LEL is the lowest concentration of a material's vapor in air that will support combustion. For a spill of a petroleum product with a low flash point, flammability (explosion) limits must be measured at the accident site to determine if there is a fire or explosion hazard. Many gas monitors also measure oxygen levels. Response operations can only proceed once safe working conditions are assured.

4.2.4 Viscosity

High viscosity (e.g., weathered, low API Gravity crude oil) limits response options. While mechanical recovery may be possible, dispersion and in-situ burning are usually less effective. If dispersant application is to be attempted on viscous oils, trials should be carried out prior to full application and only dispersants formulated for use on heavier oils should be considered.

4.2.5 Wax Content

High wax content in crude oils can limit the selection of appropriate countermeasure equipment as waxes will tend to crystallize at low temperature, increasing viscosity (see Pour Point).

4.2.6 Pour Point

The viscosity of some high wax/asphaltene content oils and many weathered crude oils can reach such high levels that they no longer flow at ambient temperatures. The temperature at which this begins to occur is called the pour point. Solidification of the spilled oil rules out most response options except for solids-handling equipment and certain special pumps.

4.2.7 Solubility

Most petroleum hydrocarbons have low water solubility. Other products, such ethanol, are soluble as well as volatile and flammable and often cannot be recovered once spilled on water.

4.2.8 Specific Gravity (Liquid)

Petroleum hydrocarbons generally have a specific gravity less than that of water and will therefore float. However, some hydrocarbons, such as bitumen and asphalt, are normally heavier than water. Weathered Bunker C, some crude oils, and other heavy fuel oils can also sink over time after being spilled rendering conventional response options inapplicable.

4.2.9 Specific Gravity (Vapor)

The vapors of most hydrocarbon fuels are heavier than air. This affects response activities when vapors accumulate as the result of booming operations, confined spaces, or other vapor-concentrating factors. The health and safety of response personnel must then be considered in flammable or low-oxygen atmospheres.

4.3 Forecasting Slick Drift

Oil slicks drift under the effect of wind and surface currents. The combined effects of currents and approximately 3–5% of the wind velocity are vectorially additive (Figure 4-2). Oil spill trajectory models can be useful in forecasting slick movement. Generally, the wind component plays a greater role in oil coming ashore than the current. A key source of information during spill response is local knowledge. Mariners, fishermen and nearby residents can be asked to assist in determining the expected direction of movement of slicks.

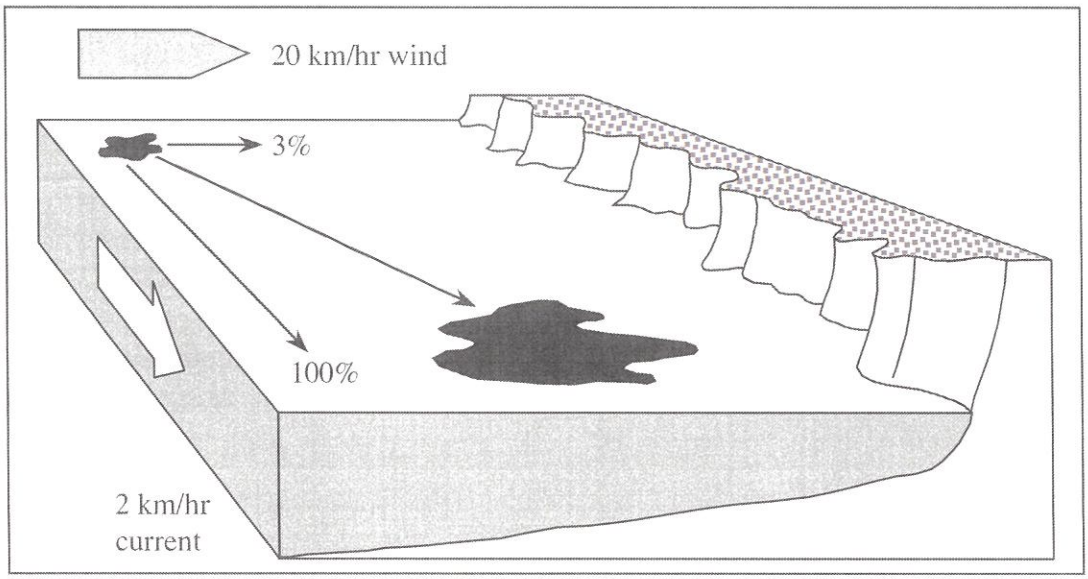

Figure 4-2 Movement of Oil on Water

In the above example, the tidal and wind-driven current vectors must be added to estimate when a slick might reach a shoreline. The direction "to" for current and "from" for wind should be noted (e.g., current *to* the east and wind *from* the north).

Oil spill models have been applied to predict or forecast the movement of surface slicks and identify areas, amenities, and biological resources that have a higher probability of spill impacts. The priority areas that might be affected by spilled oil will require the application of various countermeasure options for protection. Because oil spill trajectory models are complex and selection of appropriate input data (e.g., oil property and environmental information) is important, modeling slick trajectory and behavior should be conducted by experts. The participation of persons with local knowledge is critical in this process if accurate depictions are to be made of tidal fluctuations and patterns, shore types, and resources at risk (including seasonal aspects).

4.4 Estimating Slick Volumes

The volume of oil spilled should be estimated using as many methods as possible. Methods for estimating spilled volume include:

- The rate of flow through a pipeline and the duration of spill before shutoff
- The size and number of cargo tanks breached on a grounded vessel
- The color and size of slick areas

Estimating oil volume based on the color and size of slicks is complicated due to the complexity of slicks, their geometry and other factors. Observer experience will have a marked effect on the accuracy of estimates. The following rules should be considered when estimating slick volumes:

- Slick thickness can vary considerably even in a single slick. If there are dark brown or black patches, most of the oil is located in these darker areas.
- Colored or silvery bands indicate extremely thin slicks; these colors can often be seen at the borders or outer areas of thicker slicks.

Table 1-4 can be used to estimate slick volumes based on their estimated area and appearance. As discussed in Section 1.7, there is high variability in these reported thicknesses and they should only be used for estimating order of magnitude amounts of oil. Using them to estimate amount of oil spilled can be very inaccurate.

4.5 Visual Observation and Photography

Visual observation and aerial photography have been used effectively in open water for identifying and tracking oil spills. The volume and properties of spilled oil can be estimated using color and area measurements from an aerial photograph. Aircraft used for aerial observation must allow good all-around vision and carry suitable navigational aids. Fixed wing aircraft should be used for long range observation. Helicopters are best for near-shore waters and coastlines. For best coordination, observers should sit on the same side of the aircraft as the pilot. The direction of the sun may dictate the best direction to fly a search pattern. The search altitude is generally determined by the visibility. In clear weather, 500 meters (1640 feet) is optimal for maximizing the scanning area without losing detail. Visual observations and the use of conventional cameras can be hindered by lack of visibility due to weather conditions, including rain, fog, and darkness. Oil can be difficult to visually detect in water with algal blooms or high levels of sediment as well as over kelp and seagrass beds. Additional information on aerial observation can be found in Chapter 16.

Ground-truthing (i.e., verifying data at the water surface) is usually used to confirm visual sightings of slicks. In general, silvery and rainbow-colored sheens are not amenable to removal by skimmers, chemical dispersion, or in-situ burning, because of their thinness. Response options should be focused on slicks that are brown to black in color.

There is a wide range of cameras available that are mainly used for mapping purposes but that also can be applied to oil spills. To give contrast to visible imagery so that the darker–color thick slicks can be distinguished from iridescent sheens, cameras can be equipped with a horizontally-aligned polarizing filter and set at 53° from the vertical (the "Brewster angle"). In this way, light reflected from surface oil is photographed. Television cameras can be similarly used for spill work. Scanners in the visible spectrum are also used as oil sensors. In the past, the advantage of such scanners was their ability to produce digitized signals. However, digital cameras and recorders are now readily available that offer similar capabilities.

4.6 Tracking Buoys

Tracking buoys can be used to study current patterns. This information can be useful in predicting the trajectory of an oil spill. Several tracking buoy designs have been developed including radio- and satellite-tracked units.

4.7 Remote Sensing

There are a number of airborne sensors available to assist in the detection and mapping of spills. Operation of airborne sensors and interpretation of results requires highly trained personnel. The most commonly employed and most practical sensors are infra-red (IR) , ultra-violet (UV), and side-looking airborne radar (SLAR). A combination may be used to overcome the limitations of individual sensor types.

4.7.1 Infrared Sensors

Oil absorbs solar radiation and re-emits infrared (IR) radiation at a wavelength different than that of the surrounding water; therefore, oil spills in open water can be detected using infrared cameras. Such cameras are commercially available and comparatively easy to use. New systems are sold that can allow data logging, position determination and data transmission. Infrared video, in addition to true color video and photography, has been found to be a useful tool for determining and documenting the location of oil spills.

The application of IR sensors is limited by low cloud cover (or "ceiling"). However, they can be used at night in clear skies. Also, many other sources of sea surface temperature variation (e.g., tidal currents, river outflows, industrial cooling water effluent, sewage outfalls, etc.) interfere with this remote-sensing technique. Still, the merits can often outweigh the disadvantages, and IR can be useful in tracking large, coastal oil spills.

4.7.2 Ultraviolet Sensors

Oil slicks reflect ultraviolet (UV) radiation, even in thin layers, making it possible to map oil slicks using ultraviolet sensors. Due to light interference from sun reflection, waves and biological material, ultraviolet images are best used in combination with infrared images to provide a more positive indication of the presence of oil. UV techniques are applicable only to daytime operations.

4.7.3 Laser Fluorosensors

Laser fluorosensors work on the principle that many compounds, such as oil, absorb ultraviolet light and re-emit some of this energy in a distinctive visible wavelength. Airborne systems are capable of classifying oil and other marine pollutants in day- light as well as at night on water, in broken ice conditions or on solid ice. More recent developments in this technology allow the production of detailed map-based oil contamination information by overlaying color-coded markers of oil contamination on video images. A dedicated aircraft is often needed for fluorosensor instrumentation.

4.7.4 Radar

Radar can be used to detect oil slicks due to reflective differences in the radio signal sent to and received by an oil-free water surface and a surface that is wave-dampened by oil. Interferences, however, include certain current patterns, ice, slicks associated with freshwater or biological activity, wind-calmed or wavy water, vegetation, and various effluents

Side-looking airborne radar (SLAR) and synthetic aperture radar (SAR) are two types of systems that have application to oil spills. Both can be used for quick coverage of large areas and may be useful in detecting oil slicks in open water. They work in darkness, and through fog and clouds. SAR is capable of much greater range and resolution than older SLAR technology.

4.7.5 Satellite Remote Sensing

Satellite sensors have application to oil spills and have been applied to many situations. Systems such as LANDSAT and SPOT have been tried. Two factors, however, combine to lower the probability of detecting a spill by satellite. These are the frequency with which the satellite passes over the spill site and the reliance on clear skies to "see" the spill.

Satellites with SAR (e.g., RADARSAT) provide an indication of possible pollution and its location and dimensions. SAR is not limited by the presence of clouds. It requires considerable time to collect and transmit satellite data, which may affect its usefulness in response operations. Additionally, it takes time to interpret the results to ensure that slicks are identified as being distinct from other elements of the imagery.

4.7.6 Surveillance and Tracking of Subsea Oil

Oil spills may require surveillance and tracking of oil that does not reach the water surface, but instead may be entrained at depth. There are two mechanisms that would cause this to happen:

- the oil that is released has a greater API gravity than the water and/or
- oil droplets are small enough (<70 μm) to prevent any appreciable rise through the water in the event of subsea dispersant use.

Heavier oils are more likely to sink and be found at the bottom than lighter oil. Oils at the bottom may become covered by sediment. If this occurs, surveillance methods could include sampling by ponar sediment grabs, sediment cores, and scuba diver 'spot' checks. For plumes in the water column, surveillance methods depend on the expected size and concentration of the plume. Methods can include side scan or multibeam sonar or a laser light scattering (e.g., LISST). The use of ROV, AUV and glider platforms is becoming increasingly frequent for oceanographic surveys in the water column. These platforms can be fitted with a variety of sensors and cameras.

4.7.7 Surveillance and Tracking of Oil under Ice and Snow

The current practice is to drill numerous boreholes into ice over water and then conduct extensive sampling to map the oil's location. Oil may rise up boreholes for visual detection. Slick mapping can be aided by using information gathered as to quantity of oil observed in boreholes plus the number of boreholes where oil is observed.

There are two remote sensing techniques that hold promise in the near future: high-frequency ground penetrating radar (GPR) and nuclear magnetic resonance (NMR). Both may allow a faster rate of sampling, and subsequently greater spatial coverage.

In either manual or remote sensing, the use of markers to track the location of the spill as ice moves is recommended. Markers also can be used to delineate the perimeter of oil spilled to land under snow and ice conditions.

Tracking oil beneath floating ice may become a priority when active response measures are not possible. Place radio and/or satellite position buoys strategically in the oil deposition zone to monitor ice movements. Place pylons with light strobes on ice floes in the oil slick to assist aerial tracking. Conduct aerial reconnaissance using visual observations and remote sensing devices (e.g., airborne FLIR: forward-looking infrared).

4.8 Material Take Off (MTO) List

Table 4-3 Material Take Off (MTO) List for Tracking and Surveillance

Equipment	Use
Still image and true color video cameras	Photographing spill
Tracking buoys	Tracking slick
Remote sensing equipment	Detecting slick on water surface, in the water column, and beneath snow and ice
Trajectory and fate oil spill models	Predicting slick movement and weathering
Computers	Running oil spill models, collecting photographic images, performing calculations, and communications
Aircraft	Slick spotting
Radios	Communication among vessels/aircraft
GPS	Identifying slick position

5 Boom

5

5.1 Introduction

A boom is a floating physical barrier used to control the movement of oil. Boom is typically the first mechanical response equipment taken to a spill site. It is used to 1) contain slicks for removal by skimmers or burning, 2) deflect or divert slicks towards a collection area or away from sensitive resources, 3) exclude slicks from selected areas and protect sensitive shorelines and amenities, and 4) ensnare oil by the addition of sorbent material. Boom is manufactured in a wide variety of designs, sizes, and materials for different applications. Personnel responsible for selection and use of boom should:

- Understand the function of basic components and ancillary fittings common to most boom.
- Identify the boom in terms of its expected location of use, water conditions, and spill response operation.
- Consider the listed design factors that affect a boom's performance including its durability, storage, deployment, and oil containment potential. Manpower requirements also need to be evaluated.
- Select an appropriate size of boom according to environmental conditions and expected performance.
- Consider which boom types can be most effectively used on a spill. Refer to data for each boom type, which includes a description, recommended uses, and operational considerations.
- Consult the manufacturer-supplied data to obtain technical specifications for specific boom models.
- Consult ASTM Standards for information on boom connectors and other standardized information.

5.2 Boom Components and Fittings

Boom has four basic components (Figure 5-1): flotation, skirt, tension member(s), and ballast. Freeboard and draft are the portions of a boom's flotation and skirt above and below the waterline, respectively.

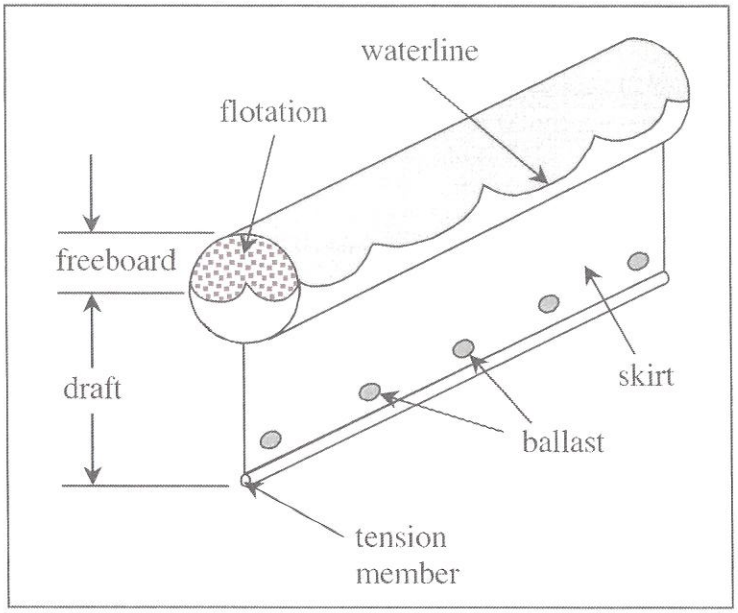

Figure 5-1 Boom Design

Flotation

- Flotation positions the boom at the water surface.
- Buoyancy chambers usually contain foam or air.
- Heavier boom used in rough, offshore conditions requires more flotation than lighter boom used in calm, nearshore or inland waters.

Skirt

- The skirt is intended to prevent oil from escaping below the boom.
- Forces from currents acting on a boom increase with skirt depth and can cause skirt failure (i.e., entrainment), allowing oil to escape.

Tension Member

- Tension members bear the load imposed by towing, winds, waves, and currents.
- Chains, cables, or webbing that run the length of a skirt or flotation are used.

Ballast

- Ballast (weighting material) helps keep a skirt vertical in water.
- Ballast often consists of a chain, wire cable, or weights located along a skirt bottom. The chain or cable could also serve as a tension member.

Freeboard

- Boom freeboard prevents splashover of oil.
- Wind forces on a boom increase with freeboard surface area. If freeboard exceeds 4–8 in (10–20 cm), boom performance can be adversely affected by high winds (typically 20 knots (kts) or 37 km/hr).

5

Draft

- Boom draft prevents oil from escaping under a boom in low current conditions.
- Shallow draft skirts reduce tension on a boom.

An understanding of the function of not only basic components of a boom, but also its auxiliary fittings or features, is required so that specific operational needs can be met:

Anchor Points	Eye bolts on end connectors along a lower tension member used to secure anchor or mooring lines.
End Connectors	Connectors join sections of boom to one another, to accessory devices, or to skimmers. ASTM F962 standard connectors are recommended to insure uniform inter-connection with other booms.
Lifting Points	Attachments to an upper tension member of a boom are used to lift it by helicopter, crane, or davit.
Stiffeners	Vertical members in flexible gaps between flotation elements add stability to some boom, particularly flat, internal flotation boom.
Handholds	Handholds facilitate manual deployment, retrieval, and storage.
Towing Devices	Wire towing bridles and paravanes (floating tow connectors) prevent a boom from being twisted and damaged when it is towed.

5.3 Operational Factors

Various other performance and design factors should be evaluated to determine which boom types work best for a particular application.

5.3.1 Roll Stiffness

Roll stiffness is the resistance of a boom to turnover in high currents and winds. Roll stiffness can be increased by adding ballast to the bottom of a boom skirt or by providing a flotation member above the vertical center of gravity of a boom. Pressure-inflatable boom exhibits high roll stiffness.

5.3.2 Heave Response

Heave response (boom conformance) is the ability of a boom to conform to waves and minimize oil losses due to splashover and underflow (bridging of waves). Self-inflating and pressure-inflatable boom have good heave response as does internal foam flotation boom with relatively short flotation members. Boom with rigid flotation or rigid skirts generally do not exhibit good heave response.

5.3.3 Freeboard and Skirt

Freeboard height and skirt depth should be optimized when selecting boom. Increased freeboard will generally decrease the probability of boom failure due to splashover; however, it will tend to lower the roll stiffness of a boom in high winds. Similarly, an increased skirt depth will decrease the probability of oil escaping under a boom in slow currents while oil will tend to break away and escape under a boom in fast currents due to entrainment, regardless of skirt depth. Increased skirt depth will increase the loading on a boom and will result in decreased heave response.

If deployment in unprotected water is anticipated, a boom that has high reserve buoyancy (weight of water displaced by a boom minus boom weight) should be used. Reserve buoyancy is also commonly expressed as buoyancy:weight ratio (boom buoyancy divided by boom weight).

5.3.4 Tensile Strength and Puncture Resistance

Tensile strength and puncture resistance are important factors to consider when open water deployment is anticipated, or when extended lengths of boom will be towed over long distances. Deployment in areas with debris requires high tensile strength and good puncture resistance of the boom fabric. Fence boom with conveyor belt skirts and durable floats perform well in these conditions. Generally, the fabric and the boom tension members combine to bear the forces acting on the boom.

5.3.5 Ease of Storage and Deployment

Ease of storage, deployment, and retrieval must be considered when choosing boom. Flat and inflatable boom can be stored compactly on a reel, on the deck of a vessel, or in a container; however, an air blower must be used to deploy most pressure-inflatable models. The deployment and retrieval of any boom require examining the potential location of its use and corresponding needs for personnel, vessels, and ancillary equipment.

5.3.6 Other Features

Important aspects that relate to operational considerations when selecting boom include the following:

- The volume occupied per unit length of a boom so that storage requirements can be planned for a designated space or reel.
- The number, type and quality of auxiliary components such as connectors, anchor points, and lifting points.
- High visibility boom material (e.g., yellow and international orange) as well as use of reflective tape and warning lights, particularly if a boom is to remain deployed at night.
- Smooth surfaces to prevent oil losses through vortices and to facilitate cleaning.
- Design of flotation, seams, bridles, stiffeners, and tension members for ease of use and cleaning, and to deflect debris.
- The durability of boom material (including the use of UV protection and marine growth inhibitors).

5.4 Boom Failure

There are five basic types of operational boom failure:

- Entrainment
- Drainage
- Splashover
- Submergence
- Planing

Each type of failure is discussed below.

5.4.1 Entrainment Failure

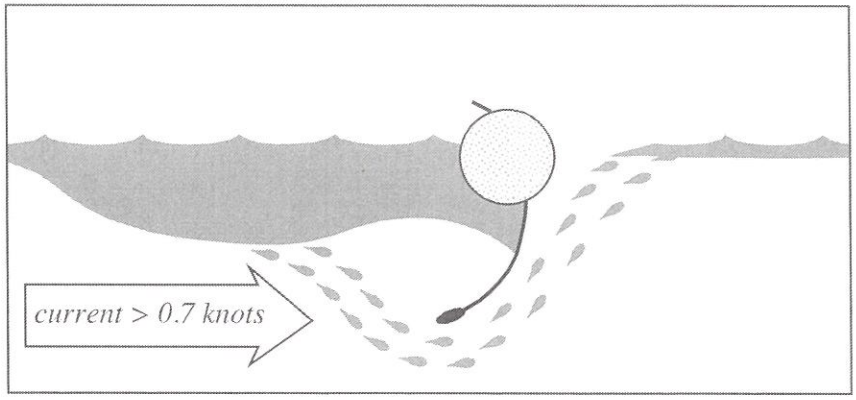

Figure 5-2 Entrainment Failure

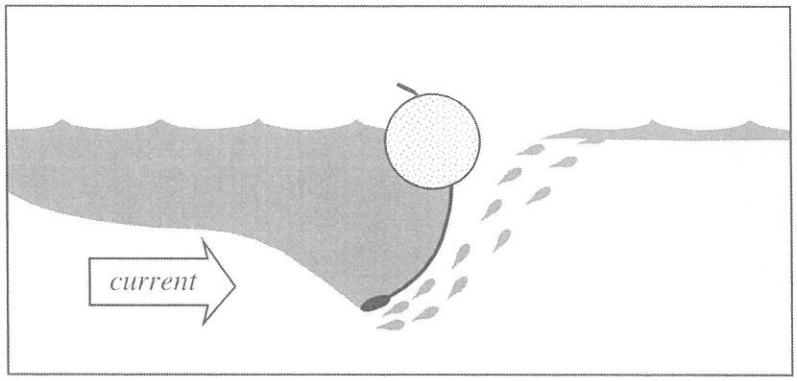
Entrainment failure generally occurs at current velocities between 0.7 and 1.0 kts (0.4–0.5 m/s). A headwave forms upstream of a boom and turbulence occurs on the downstream side of a headwave. This turbulence causes oil droplets to escape under a boom. The amount of oil lost during entrainment failure depends on the thickness of oil in a headwave. The velocity at which a headwave becomes unstable and oil droplets flow under a boom is called the critical velocity. Critical velocity is a function of current velocity and waves and is the component of water speed perpendicular to the boom. Entrainment failure may be prevented by deploying boom at an angle less than 90° to the direction of flow or by using multiple porous boom designed to operate in fast currents.

Boom deployment angle as a function of current velocity is approximately:

1 knot: 45-90° **2 knots: 20-30°** **3 knots: 15-20°** **4 knots: 10-15°**

5.4.2 Drainage Failure



5

Figure 5-3 Drainage Failure

Drainage failure rarely occurs. It can happen when a skirt boom is used to hold so much oil that oil flows down the face of the boom skirt, escaping to the other side. Increasing skirt depth is not usually a solution since it increases the potential for planing failure (Section 5.4.5).

5.4.3 Splashover Failure

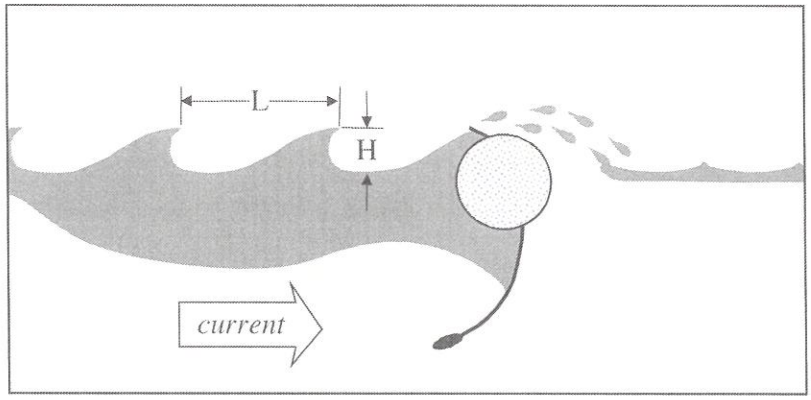


Figure 5-4 Splashover Failure

Splashover failure may occur in choppy water when wave height (H) is greater than boom freeboard and the wave length:height (L/H) ratio is less than 10:1. Most booms, however, perform well in gentle, rolling swells, even when the wave height is much larger than the freeboard.

5.4.4 Submergence Failure

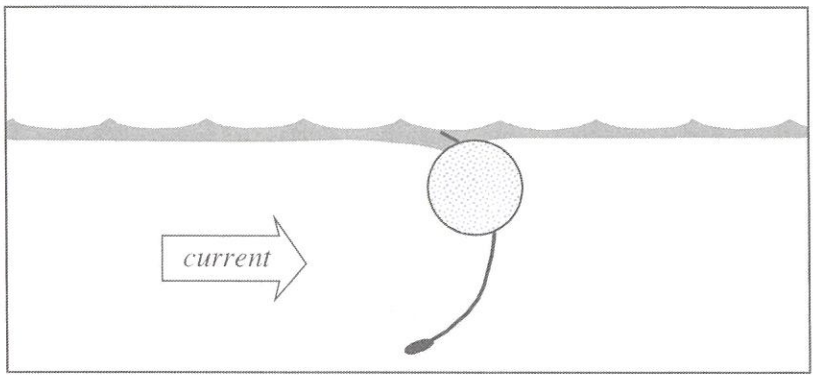

Figure 5-5 Submergence Failure

Submergence failure may occur when a boom is deployed or anchored in a fast current or is being towed too fast. The tendency for boom to submerge at a given speed is determined by the boom's reserve buoyancy (the buoyancy in excess of that required to keep a boom afloat in still water). Higher reserve buoyancy reduces the tendency to submerge. Submergence failure is not common because entrainment failure usually occurs at a much lower speed.

5.4.5 Planing Failure

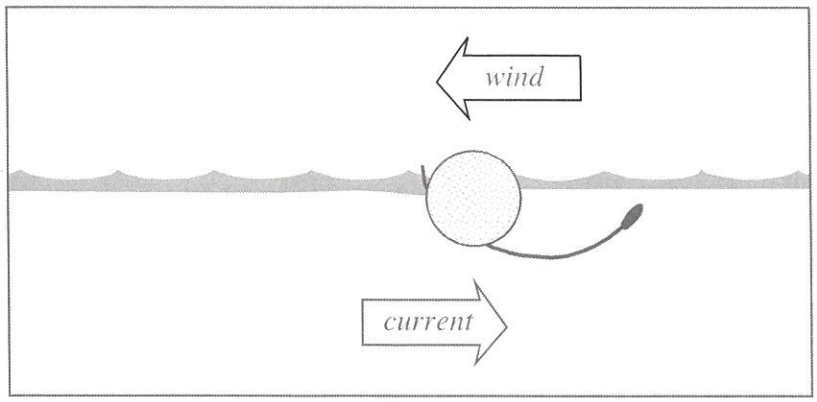

Figure 5-6 Planing Failure

A strong wind and strong current moving in opposite directions may cause a boom to heel flat on the water surface. The resulting loss of oil is called planing failure. This failure is most likely to occur when a boom has inadequate ballast or when an internal tension member is near or above the waterline.

5.5 Boom Application

Boom that incorporates the previously described features is sold in a wide variety of models for use in harbors, coastal waters, offshore areas, lakes, and rivers. Their performance ranges from excellent in calm, low current waters to poor in high wave, wind, and current conditions (see Table 5-1).

Table 5-1 Boom Performance Versus Conditions

Wind	Waves	Current	Boom Performance
0–10 kts (0-20 km/hr)	Calm, swells	0–0.5 kts (0.25 m/s)	Good
> 20 kts (>40 km/hr)	< 3–4 ft (<1 m)	> 1 kt (>0.5 m/s)	Poor

Boom is available for deployment from shorelines, docks, vessels, reels, containers and platforms. Boom selection involves anticipating the following application factors:

- Mode of deployment and time likely required for launching
- Probable location(s) of application
- Deployment vessels to be used
- Possible sea and debris conditions
- Approximate duration of the operation

Boom can be classified for use in three different sea states: **calm**, **protected** and **open water**. The sea condition most directly determines the appropriate size of boom to be used. Table 5-2 shows the ranges of freeboard and draft corresponding to maximum wave heights that a boom can adequately withstand.

Table 5-2 Boom Size Versus Sea State

Sea State	Wave Height		Boom Size			
			Freeboard		Draft	
	ft	m	in	cm	in	cm
Calm	<1	<0.3	4–10	10–25	6–12	15–30
Protected	1–3	0.3–1	10–18	25–45	12–25	30–60
Open water	>3	>1	>18	>45	>25	>60

Booms are used for three primary applications:

Containment Boom is used in little or no current to isolate a spill, to control spreading, to concentrate the oil, and to facilitate its recovery by skimmers.

Deflection Boom is deployed at an angle to a drifting slick to divert oil away from sensitive areas or to a collection point. One or more booms can be used to direct a slick to an advancing skimmer for recovery.

Protection Booming is used to exclude slicks from sensitive shorelines and/or amenities. With the addition of sorbent material, booms can also be used to collect oil.

The selection of boom depends on how quickly it is needed, how easily it can be deployed and how rugged or durable it is. The speed and ease of deployment usually depend on the equipment and number of people required. For example, self-inflating boom can be deployed very rapidly either from reels or bundles; however, if extended deployment is required, a more rugged boom that is slower to deploy (e.g., pressure-inflatable) will perform better. Generally, ease and speed of deployment are tradeoffs with ruggedness and durability.

5.6 Boom Selection

Most commercially available boom can be categorized into one of four basic design types:

- Internal foam flotation
- Self-inflating
- Pressure-inflatable
- Fence

Specialty boom is available including those manufactured with sorbent and fire-resistant materials (Section 8.3), shore-sealing barriers (Sections 5.10.1 and 6.5.4), and netting to trap high viscosity or solidified oil (Section 5.10.2).

Table 5-3 rates the four generic boom types according to environmental conditions in which they will be deployed, performance characteristics, and convenience.

Table 5-3 Boom Selection Matrix

		Type of Boom			
		Internal Foam Flotation	Self Inflating	Pressure-Inflatable	Fence
Environmental Conditions	Open Water	◑	◑	○	●
	Protected Water	○	○	○	◑
	Calm Water	○	○	○	○
	High Current (>1 kt)	◑	●	◑	●
	Shallow Water (<1 ft)	○	◑	◑	●
Performance Characteristics	Operation in Debris	○	●	◑	◑
	Excess Buoyancy	◑	○	○	●
	Wave Response	◑	◑	○	●
	Strength	◑	●	○	○
Convenience Features	Ease of Handling	◑	○	◑	◑
	Ease of Cleaning	○	○	○	○
	Compactibility	●	○	○	●

Legend ○ Good ◑ Fair ● Poor

Open Water	Wave height >3 ft	Current velocity <1 kt
Protected Water	Wave height 1–3 ft	Current velocity <1 kt
Calm Water	Wave height <1 ft	Current velocity <0.5 kt

Not all boom of a particular type have the rating shown.

1 foot = 0.3048 m
1 kt = 0.5144 m/s

To derive the most benefit from the boom selection matrix (Table 5-3), follow these steps:

- Identify the most likely environmental conditions in which boom will be used. Note the boom types that have an acceptable rating (good or fair).
- Identify the performance characteristics most needed for the intended application. From the boom type chosen above, select those with an acceptable rating (good or fair) for the most important performance characteristics.
- Identify the most desirable convenience features. For the boom type chosen from steps 1 and 2 above, select the boom with the best rating in the convenience features of interest (good or fair).

When selecting a specific boom type there may be a choice of fabrics (e.g., polyester, nylon, or aramid). Several protective coatings may be available. Table 5-4 outlines the advantages and disadvantages of four common coating materials.

Table 5-4 Boom Coating Materials

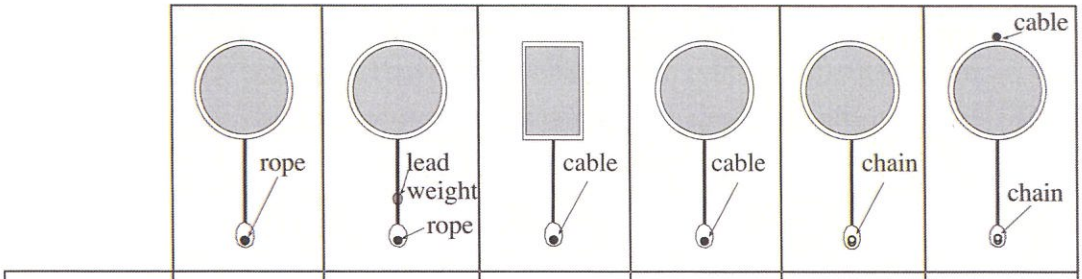
Coating	Advantages	Disadvantages
PVC	• Excellent flexibility	• Limited long-term resistance to sunlight, heat, hydrocarbons, and organics
Inhibited PVC	• Resistant to sunlight, heat, hydrocarbons and organics	• Not as resistant to organics as urethanes
Polyether urethane	• Best weather and water resistance	• Not as resistant to organics as polyester urethane
Polyester urethane	• Best resistance to organics	• Not as weather-resistant as polyether urethane

Once installed, boom requires continuous tending, particularly in locations of reversing tidal currents. Operational planning should factor in time for boom tending activities.

5.7 Types of Boom

Sections 5.7.1 through 5.7.4 compare variations of the 4 major types of boom. Wave following, ease of deployment, and oil retention are three characteristics used in the comparison. Advantages and disadvantages as well as recommended uses and operational considerations are also discussed. For overall performance of each of the 4 types of boom, refer to Table 5-3.

5.7.1 Internal Foam Flotation Boom



Boom Number	1	2	3	4	5	6
Wave Following	○	○	●	○	○	○
Ease of Deployment	○	○	○	○	○	○
Oil Retention (0–6 ft waves) (0–2 m waves)	◑	◑	◑	○	○	○

Legend ○ Good ◑ Fair ● Poor

Figure 5-7 Internal Foam Flotation Boom

The advantages and disadvantages of this boom type, as numbered above, are shown below.

Boom Number	Advantages	Disadvantages
1	• Lightweight when no ballast used	• More likely to fail without additional strength members (bottom rope is a strength member)
2	• Lead weights less likely to corrode during long immersions • Better roll response with lead ballast	• Holes in fabric where lead weights are attached may be failure points
3	• Rectangular float can be bent on a small reel	• Poor wave following
4	• Strong due to cable for strength and ballast • Better roll and heave response than rectangular flotation	
5	• Chain gives strongest tension member and heaviest ballast	
6	• Top cable gives more stability and added strength in currents	

5.7.1.1 General Comments

- Internal foam flotation boom is generally the most widely used and available boom.
- PVC or polyurethane-coated fabric encloses flexible foam flotation.
- Ballast and tension members may be enclosed within the fabric.
- Durability varies depending on the material and strength of the fabrics.

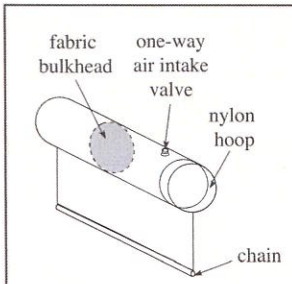
5.7.1.2 Recommended Use

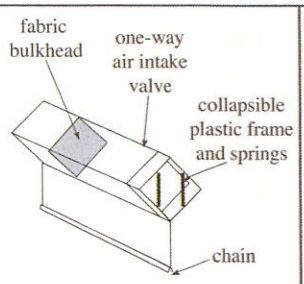
- Use for containment of oil or deflection of slicks in low currents (<1 kt or 0.5 m/s).
- Select for use where adequate boom storage facilities are available. Most models are normally stored in containers or on the deck of boom deployment vessels although, in some cases, larger diameter reels are also used.
- Generally, terminal facilities and marinas can be protected using this type of boom.
- Extended deployment (several weeks) in waves up to 3 ft (1 m) is feasible.

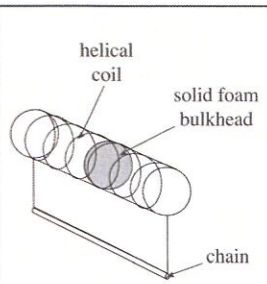
5.7.1.3 Operational Considerations

- In areas where currents are more than 0.5 kts (0.25 m/s), select round flotation booms with top and bottom tension members for deflecting and containing slicks.
- In slower currents (<0.5 kts or 0.25 m/s), round flotation booms with only a bottom tension member can be used for deflection/containment.
- In quiet, shallow water, it is reasonable to expect that booms with square or rectangular internal flotation can be successfully used.
- Long lengths of boom (several hundred feet) can be deployed, which can sustain loads usually encountered during most nearshore operations.
- The bottom chain pocket could abrade if deployment is conducted from concrete boat ramps, dock surfaces and roadways.
- High durability fabrics such as polyester, nylon or aramid should be selected for permanent booming applications.
- Straight-line towing (streaming) is possible at low speeds (up to 0.5 kts or 0.25 m/s) to the location of use.

5.7.2 *Self-Inflating Boom*







Boom Number	1	2	3
Wave Following	○	○	○
Ease of Deployment	○	○	○
Oil Retention (0–4 ft waves) (0–1.2 m waves)	○	○	○

Legend ○ Good ◑ Fair ● Poor

Figure 5-8 Self-Inflating Boom

The advantages and disadvantages of this boom type, as numbered above, are shown below.

Boom Number	Advantages	Disadvantages
1	• Sealed compartments • Can be compacted on racks or pallets	• Cannot be reeled • Splashover due to round freeboard without fin • Oil in the air valve could prevent it from functioning • If a valve malfunctions, that section can lose buoyancy
2	• Can be reeled and packed on pallets • Most compactible of all three types • Sealed compartments	• Loses freeboard due to water and wind forces turning the square freeboard on its side • Internal springs present maintenance problem • Oil in the air valve could stop it from functioning • Repacking is difficult due to need to extend springs
3	• Stores on reel • Simple to use • No valves, only air ports	• Water can pass from one compartment to the next over the air slot in the bulkhead

5.7.2.1 General Comments

- Self-inflating boom is excellent for handling and storage, and it is quickest to deploy.
- PVC or polyurethane-coated fabric contains flotation chambers that compress during storage and inflate with air through intake valves upon deployment.
- Built-in frames, springs, or helical metal coils can assist self-inflation.
- Fabrics have relatively high tensile strength, but can be punctured by debris or other sharp objects, thereby resulting in loss of buoyancy.
- Fabric tearing during deployment can also result in loss of buoyancy.
- Long-term problems, such as corrosion and collapse, have occurred with various internal expansion mechanisms.
- This boom is well-suited for air transportation to remote locations.
- This boom conforms well to waves.

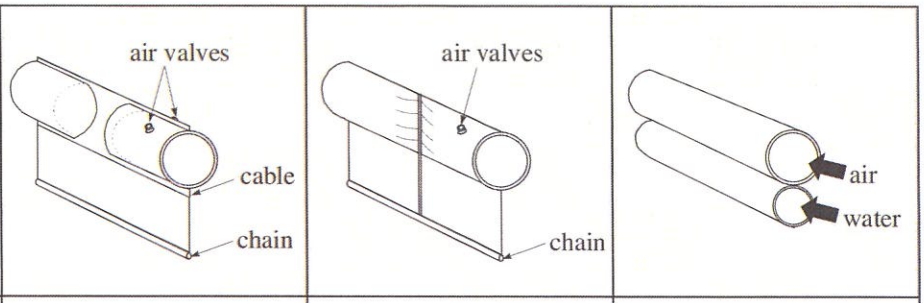
5.7.2.2 Recommended Use

- This type of boom is designed for rapid deployment situations.
- This boom type has been used for stationary containment or deflection of slicks in calm, low currents and nearshore waters, i.e., in harbors and at other sites with wave heights of up to 3–4 ft (1–1.2 m) and currents up to 0.5 kts (0.25 m/s).
- Self-inflating boom may be suitable for use at facilities or on vessels with limited storage space and on compact reels (some boom models only).

5.7.2.3 Operational Considerations

- When deployed, each section must be fully extended so that the boom has sufficient flotation towards connectors to keep them at full freeboard.
- Limit single deployment to lengths of 500–1,000 ft (150–300 m).
- Plan to monitor and tend frequently once deployed to ensure that flotation is maintained.

5.7.3 *Pressure-Inflatable Boom*



Boom Number	1	2	3
Wave Following	○	○	○
Ease of Deployment	◑	◑	○
Oil Retention (0–6 ft waves) (0–2 m waves)	◑	○	◑

Legend ○ Good ◑ Fair ● Poor

Figure 5-9 Pressure-Inflatable Boom

The advantages and disadvantages of this boom type, as numbered above, are shown below.

Boom Number	Advantages	Disadvantages
1	• Divided air cylinders result in only partial loss of freeboard if the boom is punctured • Can be deployed manually • Can be reeled	• Slow to deploy due to each half cylinder having to be inflated separately
2	• A single large air cylinder decreases inflation time • Can be reeled	• Puncture causes total loss of freeboard in section of boom • Heavy to deploy, recovery requires winch
3	• A reel deployment and recovery system makes this boom easy to deploy and recover • Some versions have an air manifold on top of flotation and check valves in segments so continuous air compressor is not required • Excellent shore seal	• No bottom tension member • Requires powered reels to recover boom • Needs continuous power for air compressor and water pump while deployed • Puncture causes total loss of boom • Very difficult to re-position once lower boom has been filled with water

5.7.3.1 General Comments

- Pressure-inflatable boom allows for compact storage and high buoyancy to weight ratio.
- Well suited for air transportation to remote locations.
- Fabric is PVC, neoprene, nitrile rubber-nylon, or polyurethane-coated material.
- Up to several hours might be required to inflate sections of some open water models. Other protected water models inflate much more quickly.
- Durable fabrics are now generally used in this boom type versus earlier models.

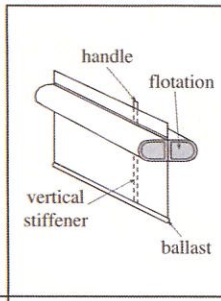
5.7.3.2 Recommended Use

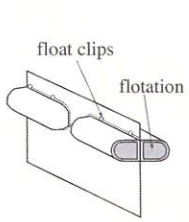
- For coastal and offshore operations for both stationary and towed boom configurations.
- For use where storage space is limited. Compact reel storage is possible.
- For use when fast deployment and retrieval are not priorities.
- For situations where wave heights can reach 6 ft (2 m).
- For use where wave conformance is a priority.
- Pressure-inflatable boom is generally not suitable for deployments longer than 1 week due to the potential loss of air; more durable models are exceptions.

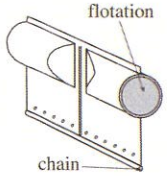
5.7.3.3 Operational Considerations

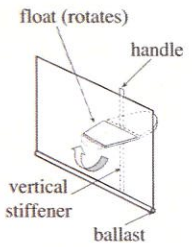
- On-site air blower and power supply are required for inflation.
- Plan on sufficient working platform that can accommodate boom, auxiliary equipment, and adequate personnel.
- Monitor and tend frequently once deployed to ensure that flotation remains intact.
- Large models require a mechanized handling system and an adequate number of personnel for deployment and recovery.
- Some manufacturers offer a non-standard piano hinge connector that may cause problems when (1) the hinge is bent or (2) the boom must be connected to other booms.

5.7.4 Fence Boom









Boom Number	1	2	3	4
Wave Following	●	●	●	●
Ease of Deployment	○	○	●	○
Oil Retention (0–2 ft waves) (0–0.6 m waves)	○	○	○	○

Legend ○ Good ◑ Fair ● Poor

Figure 5-10 Fence Boom

The advantages and disadvantages of this boom type, as numbered above, are shown below.

Boom Number	Advantages	Disadvantages
1	• Heavy materials all molded • Good roll response	• Low buoyancy to weight ratio • Poor wave (heave) response • Difficult to deploy and recover
2	• Replaceable floats • Good roll response	• Poor wave (heave) response • Difficult to deploy and recover • Not good in debris since floats may be dislodged
3	• Lightest of fence type boom • Replaceable floats • Fairly easy to deploy	• Poor wave (heave) response • Only fair roll response
4	• Wide floats give good resistance to roll in models 3 ft (1m) in total height or less • Boom can be inverted in water to remove marine growth	• More subject to float damage and hanging up on piers, boats, etc. • Poor wave (heave) response • Difficult to deploy • Floats may retain debris

5.7.4.1 General Comments

- Fence boom with rigid or semi-rigid fabric provides a vertically stiff and horizontally flexible "fence".
- Flotation is provided by integrated-foam flotation blocks, bolted-on blocks, or outrigger floats.
- Fabric durability ranges from low to high tensile strength options, depending on intended application.
- Fence boom provides effective, long-term, low maintenance protection and/or containment.
- Some models are suitable for long-term/permanent deployment in harbors to surround vessels transferring petroleum products.
- External floats on some models may create additional water surface disturbance resulting in increased oil entrainment or splashover.

5.7.4.2 Recommended Use

- For routine or permanent deployment situations.
- Fence boom is applicable to stationary containment of oil in quiet waters or deflection of slicks in low currents of 0.5 kts (0.25 m/s). It is only suitable for low wave height.
- Use at facilities or on vessels with sufficient boom storage space.
- Fence boom is generally suitable for the protection of terminal facilities and marinas. It is sometimes used for the nearshore containment and concentration of slicks for recovery.
- Use where debris resistance is required.
- Use during extended deployment periods of several weeks or more.

5.7.4.3 Operational Considerations

- Fence boom can be towed at low speeds (up to 5 kts or 2.6 m/s) to location of use.
- Long lengths of boom (600 to 800 ft or several hundred meters) can be deployed which can sustain loads usually encountered during nearshore operations.

5.8 Boom Deployment

Before boom is deployed, the approximate length of boom required should be assembled as completely as possible either on land or on the deck of a boat. Suggested lengths of booms for various applications are presented in Table 5-5.

Table 5-5 Suggested Boom Lengths

Application	Type of Boom	Quantity
Circle a stricken vessel	Offshore or harbor, depending on sea conditions	3 x ship's length
Contain leakage from terminal operations	Calm water or harbor, depending on sea conditions	1.5 x ship's length
Use with an ocean skimmer	Offshore	500-1,500 ft (460-610 m) per skimmer
Protect entrance to estuary, stream, river, etc.	Calm water	3 to 4 x width of a water body
Bays, harbors, marshland	Calm water or harbor, depending on sea conditions	(1.5 + current in kts) x width of a water body

It is important to ensure that all boom connectors are compatible, especially when booms from multiple manufacturers are used. When ordering booms, always ensure that connectors meeting ASTM standard specification F962 are used. This will ensure that all booms can be connected to each other even if they are from different manufacturers. Check local contractors or Oil Spill Response Cooperatives to determine what type of connector is used.

Once the boom is ready, it can be launched and towed into position by boat. To ease the problems for a towing boat, a long boom can be doubled back on itself and towed out from the center point. Once that is anchored, the ends can then be towed into place and anchored. Final configuration can be arranged by setting suitable anchors or securing to permanent anchor points.

Where a boom is being used to collect oil at a shore location or protect a sensitive area, care should be taken to seal the shore end of a boom so that no oil can escape. This is particularly difficult in tidal waters and at sites where the shore is rocky or strewn with boulders and crevices.

Boom length may have to be modified after the boom has been deployed. This can be difficult to do from a vessel particularly in strong currents, high winds, or low temperatures as loose shackles, bolts, and tools can be lost over the side. Often, boom length cannot be changed once the boom is in the water, and the boom must be retrieved, reconfigured, and re-deployed.

5.8.1 BoomVane™

A BoomVane™ (Figure 5-11) is a device for deploying containment boom or dispersant spray arms into bodies of water by harnessing the power of currents in the waterway. The device can be launched from a boat or from land. When deployed from a boat, the BoomVane™ allows for a single vessel sweep system without the need for an outrigger arm. Using a series of lines, the device can be launched and retrieved which allows for quicker repositioning when needed due to debris, vessel traffic, or changing tides.

Available in four different sizes, ranging from the 0.5m Shallow, 1.0m Standard, 1.5m BoomVane™, to the largest–2.0m Ocean.

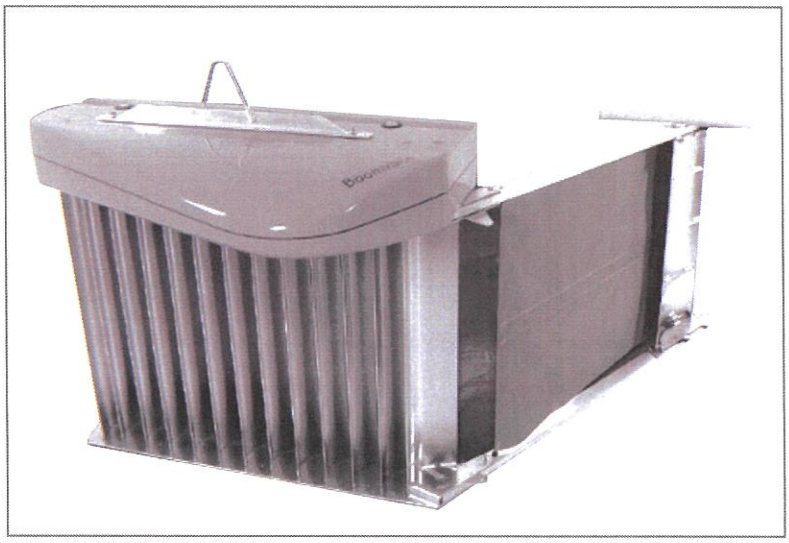


Figure 5-11 BoomVane™

5.9 Guidelines for Towing Boom

Boom is pulled by towboats in various configurations to contain and recover slicks. Boat speed is typically less than 1 knot (0.5 m/sec).

5.9.1 U-booming

Two vessels can tow a boom in a U-configuration by drifting downstream, holding in a stationary position, or by moving upstream toward the spill source.

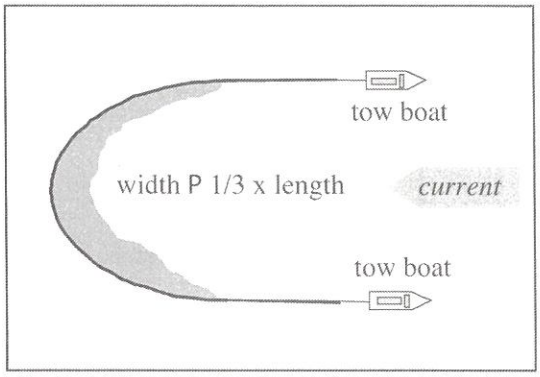

Figure 5-12 U-Booming

5.9.2 V-booming

Boom can be deployed in a V-configuration using three vessels and a skimmer. A tie-in is usually needed to maintain the V shape.

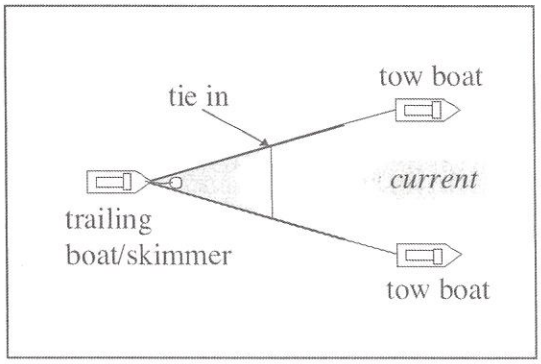

Figure 5-13 V-Booming

5.9.3 J-Booming

Boom can be towed in a J-configuration that will divert oil to a skimmer to allow simultaneous containment and recovery.

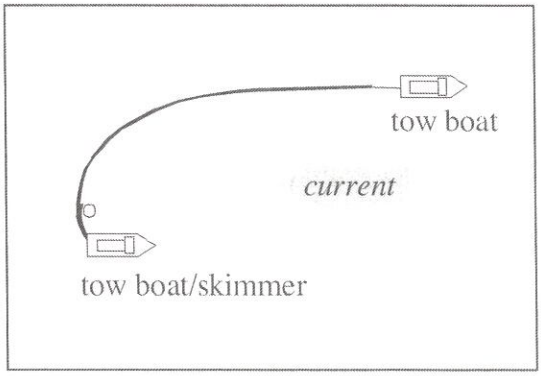

Figure 5-14 J-Booming

Table 5-6 shows the applicability of boom towing configurations for the four basic boom types in calm, protected, and open water.

Table 5-6 Boom Towing Configuration

Boom Use		Internal flotation	Pressure-Inflatable	Self-inflating	Fence
Calm Water	U/V	◑	○	◑	●
	J	○	○	●	◑
Protected Water	U/V	○	○	◑	●
	J	○	○	●	◑
Open Water	U/V	◑	○	●	●
	J	○	○	●	●

Legend ○ Good ◑ Fair ● Poor

Boom lengths of 500 to 1500 ft (150 to 460 m) are typically used when towing boom in a U, V, or J configuration to maximize the oil encounter rate. Lengths as high as 2000 ft (600 m) have been used but maneuverability is improved with shorter boom lengths.

The use of proper towing bridles or paravanes will minimize damage during towing by efficiently transferring the point load tension from the line to the connector. Towing devices prevent a boom from twisting when being towed at high speeds. Lines between boom ends and vessels should be of sufficient length to avoid sharp stress or snatching on a towed boom. Approximately 200 ft (60 m) for a 1,500 ft (460 m) length of boom is typical. When feasible, an odd number of boom sections should be used to avoid having a connector at an apex from which oil more readily escapes.

Oil concentration by towed booms can be slow in thin slicks. Boom performance can be judged visually at the apex of the U or J. Oil lost under a boom will appear as globules or droplets rising from behind a boom. Eddies behind a boom are also an indication that towing is too fast; however, sheens are usually present behind a boom even when a boom is functioning well.

Note that the apex of a boom often cannot be seen from the wheel-houses on towing vessels. Aircraft equipped with suitable air-to-sea communications can assist in directing movements and activities of vessels to ensure that they are operating in the heaviest concentrations of floating oil. Oil slicks can be more easily located from the air than from the water surface. The thickness and volume of a slick can also be estimated from an aircraft.

Maintaining proper station of the two towing vessels relative to one another requires good communication and is improved with practice. Towing in a J configuration is difficult with untrained crews. For maximum maneuverability at low speeds, the ideal towing point aboard the vessel must be determined by trial and error and may need to be altered according to wind and course direction. A towing point well forward of the stern is best.

5.10 Special Application Boom

5.10.1 Shore-Sealing Boom

In intertidal areas, or along river banks, where water levels fluctuate, shore-sealing booms can be deployed to ensure that a seal is maintained at the waterline. They can be used on mud or sand flats, but do not form an effective seal on either rough or rocky shorelines.

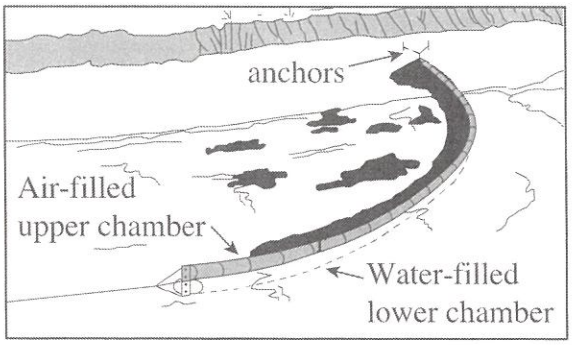

Figure 5-15 Shore-Sealing Boom

5.10.2 Netting Boom

Subsurface barriers are used to intercept, contain, and/or recover oil that is below the water surface. They are generally used to recover heavy oils, such as weathered or emulsified crude, tar balls, or tacky burn residue. They will not recover light, low viscosity oils that can flow through the boom's mesh.

Netting boom can usually be towed at higher speeds than conventional boom, which may allow higher recovery rates, better steering control and continuous operation of the tow vessel (i.e., the vessel can maintain its speed without stopping and starting).

Netting boom is suitable for collecting oil along beaches and shorelines with significant wave action. This type of boom may be set just below the high tide line to catch any weathered oil or emulsion that floats ashore, preventing the oil from penetrating into the soil below. The netting can be retrieved, cleaned, and reapplied before the next tidal cycle, or it can be incinerated. Note that retrieval and cleaning of oiled netting is a messy task that often requires subsequent cleaning of vessels and crew. Incineration may require government approval and/or use of an approved incinerator.

5.10.3 Current Buster® Technology

Conventional containment boom tow speed is limited due to entrainment failure that generally occurs at current speeds between 0.7 and 1.0 knots (0.4-0.5 m/s) as described in Section 5.4 Boom Failure. Current Buster® technology is able to increase the speed at which oil can be corralled to up to 5 knots towing speed with minimal oil loss. The system consists of two boom lengths extending outward to create a pocket (i.e., swath width), a debris collection area, and then a set of wave dampeners directly ahead of a pocket for oil collection, thickening, and pumping. This technology is available in multiple sizes which are constructed for specific areas of operation (i.e., nearshore, offshore and open water).

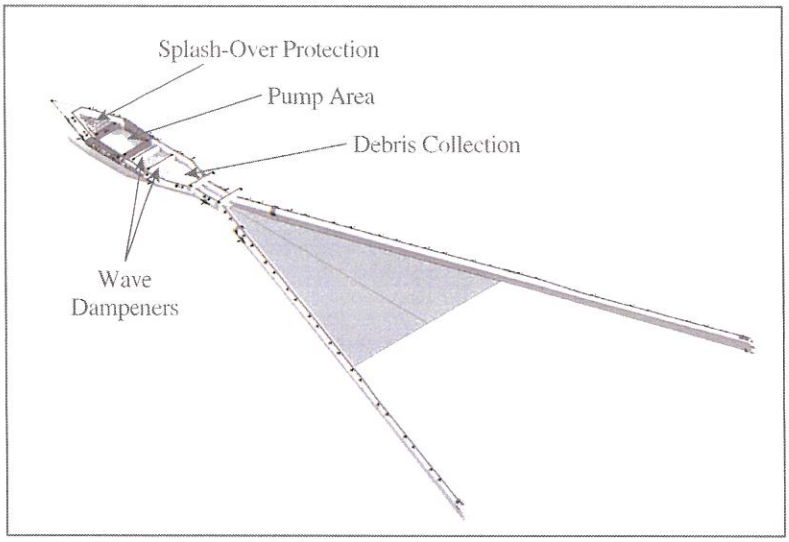

Figure 5-16 General Current Buster® Configuration

5.11 Boom Anchoring

Anchoring boom requires specific knowledge of the equipment, accessories, and techniques involved. Tide tables, local knowledge and weather forecasts should be consulted before boom is deployed, especially when it must remain overnight.

- Anchoring boom can require anchors (e.g., Danforth, Fisherman's), release lines, chains, floats, bridles, lights, and other accessories (see Figure 5-16).
- If feasible, permanent anchors can be placed at strategic sites in advance of a spill.
- Table 5-7 can be used to approximate anchor size. Local mariners can also provide guidance.
- Practice drills can help determine the type and weight of anchors most effective at specific sites.

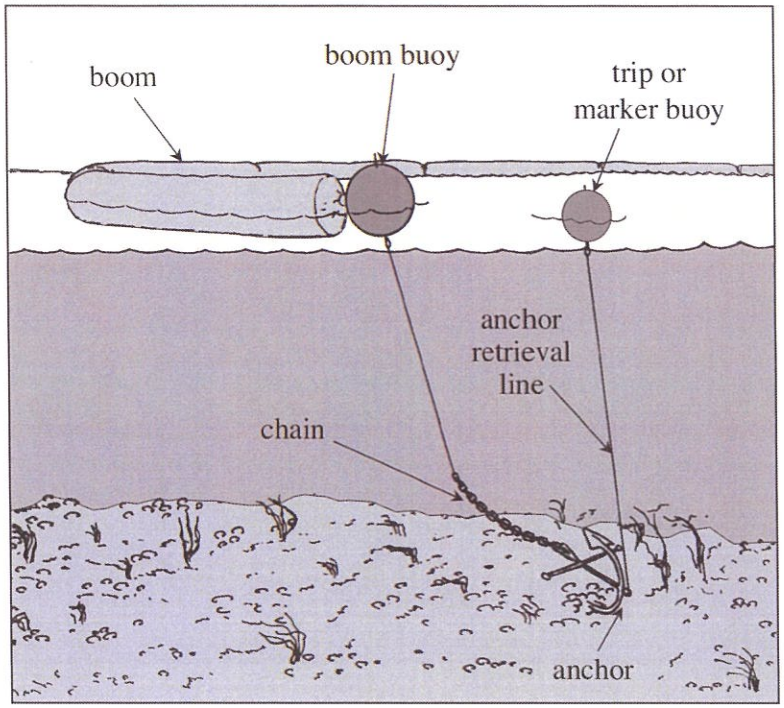

Figure 5-17 Boom Anchoring Assembly

Table 5-7 Holding Strength of Danforth Anchors

Anchor Weight lbs (kg)		Holding Strength lbs (kg)					
		Mud		Sand		Clay	
30	(15)	440	(200)	550	(250)	660	(300)
60	(25)	770	(350)	880	(400)	1,100	(500)
80	(35)	1,320	(600)	1,540	(700)	1,540	(700)

5.11.1 Anchoring in Marine Waters

The following guidelines should assist in preventing the loss or damage of boom anchors in coastal waters:

- For large boom and many containment operations in currents, it is essential to set anchors first, and then deploy and attach boom to ensure correct positioning. Smaller boom (<18 in or < 46 cm) can be easily deployed in calm water by anchoring either first or last.
- Anchor lines can be fastened directly to towing ends. If anchor buoys are used, they should be securely fastened to anchor lines.
- When booms without anchoring points are deployed, floats provide an effective means of attachment so that the boom is not pulled down with tide changes.
- When anchor points are located below the water surface, a floating line should be attached to allow ready access.
- To assist in retrieving an anchor, a trip (or marker) line can be attached to the crown of an anchor that is secured at its other end to a float of a different color than the anchor line buoy.
- Consistent color and size, e.g., 8 in (20 cm) blue top line buoys and 12 in (30 cm) red anchor line buoys, facilitate the deployment and retrieval of boom.

In non-flowing waters, boom should be anchored every 200 ft (60 m), noting the following:

- Tides and boom configuration might dictate more frequent anchoring intervals.
- The length of anchor lines (L) can be estimated using the following formulas:
  - calm water: L = 3 x water depth
  - choppy water: L = 5 x water depth
  - rough water: L = 7 x water depth

- In waves along exposed coasts, anchor lines should be at least 5 x the water depth to prevent them from snatching (i.e., being quickly pulled under the water surface when placed under tension).
- Generally, the length of line used should include sufficient slack to allow for tides, currents, and waves. This length is assessed on a case-by-case basis.
- Chain can be attached to an anchor line at its end to help set the anchor and to increase its holding capacity.

5.11.2 Anchors of Opportunity

The number of anchors available during a large spill incident is often limited. As a result many anchors of opportunity are used. Examples of anchors of opportunity include concrete blocks, metal weights and a shore sealing (air/water tube) boom.

- Lines should be firmly attached to such anchors and safe deployment procedures carefully followed so that mishaps do not occur.
- Lifting gear for concrete blocks and other large weights should be used properly, in a manner that does not compromise the stability of a small vessel, e.g., tugboat.

5.11.3 Anchoring in Currents

Deploying boom in currents of 0.5 kts (0.25 m/s) or more requires special anchoring techniques:

- Lines can be secured to shore every 30 ft (10 m) to allow the boom to be angled 30° to 45° to the current and to reduce the effective current velocity acting on the boom. Oil can then be deflected or recovered.
- Cables or ropes can be used to link boom to various anchors located on a riverbank or foreshore area.
- Trees, bridge supports, and other items can be used to anchor boom, often at pre-selected spill control points, as long as they don't represent unsafe tripping hazards. Cables or rope can be covered by rubber or run through small floats so that neither the line nor the item used as an anchor is damaged.
- At some river terminals, a boom can be permanently anchored at one end and left to float freely in the water. When needed, usually to surround a vessel transferring oil, the free end of a boom can then be readily towed into position.

5.12 Boom Washing

There is little need to wash booms used to trap oil repeatedly. However, it is necessary to clean boom under certain circumstances:

- Where boom is to be used for the protection of un-oiled areas;
- After boom has been used to contain oil freed during shoreline cleanup operations; and
- When boom is taken out of service and returned to storage.

Use of dirty boom is usually unacceptable because of the sheen it leaves behind. Cleaning small amounts of boom can be done manually in a contained area using a pressure washer wand, long handled-scrub brushes, detergent, and warm water. A containment area is necessary where the wash water is collected. After washing, booms can be wiped by hand with sorbent pads. On a good day, 6 to 12 workers can clean up to 3,000 ft (900 m) of boom.

In the event of imminent bad weather, more rapid cleanup techniques such as dispersants or shoreline cleaners may be useful options, if there is government support.

5.13 Material Take Off (MTO) List

Typical equipment needed is shown in the following MTO list.

Table 5-8 Material Take Off List for Boom

Equipment	Use
Boom	Containing oil for recovery
Anchors	Anchoring boom
Floats	Marker and trip-line buoys
Rope	Towing, anchoring
Paravanes	High-speed towing
Chain	Anchoring
Cable	Towing, positioning boom
Lights	Night-time illumination of boom
Fittings	Connecting boom, lights, anchor lines
Power supply/generator	Provide power for air blowers, pumps, etc.
Air blowers	Filling air chambers on inflatable boom
Pumps	Filling water chambers on shore-sealing boom
Vessels	Deploying, towing, and tendering boom
Aircraft	Slick spotting, positioning of vessels
Radios	Communication among vessels/aircraft
GPS	Positioning boom, documenting activities
BoomVanes™	Deploying and retrieving containment boom
Current Busters®	Increases tow speed of boom while maintaining containment characteristics

6 Shoreline Protection

6

6.1 Introduction

Every reasonable effort should be made to prevent oil from reaching the shore in order to reduce:

- Environmental impacts
- Duration of cleanup operations
- Generated wastes

If attempts to do so fail, methods to divert slicks from a more sensitive area to a less sensitive area should be employed. This section discusses various ways of keeping oil away from sensitive areas and identifies shoreline protection measures.

If oil has reached the shore, the treatment techniques outlined in Section 12 should be considered.

6

6.2 Shoreline Types

Response strategies have been developed for the various shoreline types based on their specific characteristics. The sensitivity of each shoreline type to spilled oil is indicated in Table 6-1. The shoreline types are arranged from lower sensitivity (e.g., exposed rocky headland) to higher sensitivity (e.g., salt marshes and mangroves). Near-shore habitats, such as kelp and seagrass beds, coral reefs and lagoons are included in Table 6-1 because these areas warrant special consideration in deploying protective measures.

Table 6-1 Response Considerations for Various Shoreline Types and Nearshore Habitats

Intertidal Shoreline	Response Considerations
Exposed Rocky Headlands and Wave-cut Platforms	• Wave reflections can help to keep oil offshore • Cleanup may not be required
Man-made Solid Structures and Boulder Beaches	• Wave swept, usually erosional • Natural processes will remove oil within weeks • Cleanup may not be required
Fine- to Medium-Grained Sand Beaches	• Low density of biological populations • Oil does not penetrate into the beach • Mechanical removal of oiled sand is effective

Table 6-1 Response Considerations for Various Shoreline Types and Nearshore Habitats (continued)

Intertidal Shoreline	Response Considerations
Coarse Grained Sand Beaches	• Low density of biological populations • Oil may penetrate/be buried rapidly up to 30 cm, making cleanup difficult • Mechanical removal is effective
Tundra Cliffs	• Vegetation overlies peat and permafrost • Remove oil by sorbing with peat or by other manual methods
Gravel and Cobble Beaches	• Oil may penetrate rapidly, making cleanup difficult • Cleanup should concentrate on high tide area • Oiled debris should be removed (ideally, debris should be removed prior to oil impact) • Shoreline cleaners used in some countries to speed oil removal
Riprap	• Mainly breakwaters and jetties • High pressure flushing may be effective • Any released oil must be recovered
Exposed Tidal Flats	• Low to moderate biomass • Mobile sediments, and most oil will not penetrate sediments • Natural processes will remove most oil in about one year
Exposed Vegetated Tidal Flats	• Moderate biomass • Sediments less mobile, and most oil will not penetrate sediments • Oil may persist about one year
Sheltered Rocky Shores and Clay Scarps	• Moderate to high biomass may be affected • Clay scarps may have numerous burrows and tunnels • High priority protection zones • Removal of heavy oil concentrations may be beneficial; use only low-pressure flushing
Peat Shorelines	• Often found in Arctic regions • Natural recovery is the most preferred response option
Inundated Lowland Tundra	• These are Arctic subsidence areas flooded by the sea • Cleanup can cause extensive damage • Natural recovery is least damaging and preferred

Table 6-1 Response Considerations for Various Shoreline Types and Nearshore Habitats (continued)

Intertidal Shoreline	Response Considerations
Sheltered Tidal Flats	• Large populations of animals and plants • Area should receive top priority protection from oil contact • Low wave action • Removal of heavy oil accumulation may be beneficial; otherwise, cleanup is not recommended • Oil may persist for long periods
Salt Marshes	• Most productive of aquatic environments • Very low wave energy, and high sedimentation rate incorporates oil into sediment • Oil may persist for years • Cleanup may do more damage than natural degradation processes
Mangroves	• One of the most important marine habitats • Highest priority protection area • Mangroves should not be altered by response activities • Dispersants or cleaners can be more beneficial than mechanical cleaning
Shallow Subtidal	**Response Considerations**
Coral Reefs and Lagoons	• Areas should receive high protection priority • Oil will float over reefs with minimum impact • Dispersants may be used near but not above coral reefs
Seagrass Beds	• Highly productive aquatic environment • Low wave action • Oil will float over • Cleanup may do more damage than leaving the oil to natural degradation processes
Kelp	• Highly productive aquatic environment • Will not be impacted by floating oil • Dispersants should not be applied directly above

Reference: *ASTM F-2464-12, Standard Guide for Cleaning of Various Oiled Shorelines and Sub-Tidal Habitats*, ASTM International, West Conshohocken, PA, USA, 2012.

6.3 Selection of Shoreline Protection Techniques

Selection of an appropriate protection technique for a shoreline depends not only on the type of shoreline and its sensitivity, but also on several other factors as summarized in Table 6-2.

Table 6-2 Factors Affecting Shoreline Protection

Nature of the Spill	• Amount and type of oil spilled • Time until oil contacts shore
Weather	• Present conditions • Weather forecasts
Type of Water Body	• Lake, river, canal, swamp, lagoon, estuary, ocean, fjord, bay, strait, etc.
Ecological, Economic, and Cultural Resources	• Immediate risk to resources • Seasonal considerations (nesting, spawning, ice, snow) • Fishing, tourism
Water Movement	• Erosional or depositional (high or low flow) in nature • Current speed and direction, rip tide • Tidal action: differential, frequency, tidal bore • Wave action: breaking, non-breaking
Shoreline Contour	• Water depth • Smooth, rocky, reef, island • Precipice, shelf, harbor, • Gradient, stability of sediment
Accessibility	• Land access (roads rated for passage of heavy equipment) • Water access (depth greater than boat draft and ability to operate in slick) • Air access (flat ground with <10° slope for helicopter pad)

6.4 Shoreline Protection Decision Guides

Decision guides are presented in this section to facilitate the selection of shoreline protection techniques for particular spill conditions and the waterway or shoreline type and contour involved.

The decision guides in this section are divided into two categories:

- Inland waterways (Table 6-3)
- Coastal waters and large lakes (Table 6-4)

Information on response techniques applicable to a particular type of waterway are summarized below.

Table 6-3 Decision Guide for Protecting Inland Waterway Shorelines

Lake or Pond	Minor sheen • Use sorbent boom Moderate to major visible slick • Use containment boom
Rivers or Large Streams >1.6 ft (0.5 m) deep	Currents <1 kt (0.5 m/s) • Use containment or exclusion boom Currents 1–2 kts (0.5–1.0 m/s) • Use single diversion boom Currents >2 kts (1.0 m/s) • Use cascading or fast current boom
Small Streams <33 ft (10 m) wide and 1.6 ft (0.5 m) deep	Currents <1 kt (0.5 m/s) • Use sorbent or containment boom or berms or dams Currents 1–2 kts (0.5–1.0 m/s) • Use single diversion boom or berms or dams Currents >2 kts (1.0 m/s) • Use cascading boom, fast current boom or berms or dams
Shallow Rivers or Streams <1.6 ft (0.5 m) deep	Currents 0–2 kts (0–1.0 m/s) • Use berms or dams

Table 6-4 Decision Guide for Protecting Coastal Shorelines

Straight Coastline with Sensitive Areas	Breaking waves >1.5 ft (0.5 m) • Use beach berm or containment boom outside of surf zone if feasible Breaking waves <1.5 ft (0.5 m) • Use diversion boom upstream of sensitive areas
Entrance to Bays, Harbors, Lagoons	Breaking waves <1.5 ft (0.5 m) *and* current <1 kt (0.5 m/s) • Use exclusion boom across entrance Breaking waves <1.5 ft (0.5 m) *and* current >1 kt (0.5 m/s) • Use angled diversion boom at or inside entrance where currents are reduced Breaking waves >1.5 ft (0.5 m) • Use containment boom outside of entrance
Narrow Tidal Channel	Current <1 kt (0.5 m/s) • Use sorbent barriers or exclusion boom across entrance Current >1 kt (0.5 m/s) • Use diversion boom across channel

Note: When wave amplitude exceeds 1.5 ft (0.5 m) or currents exceed 3 knots (1.5 m/s), protective booms should be moved to calmer waters if available. It will be very difficult for a single boom to contain oil.

6.5 Specific Protection Measures

Physical protection techniques that can be used to control or contain floating oil slicks are described in the sections below. Four booming techniques, two earthen barrier types, and use of a passive, sorbent boom are presented below.

6.5.1 Exclusion Booming

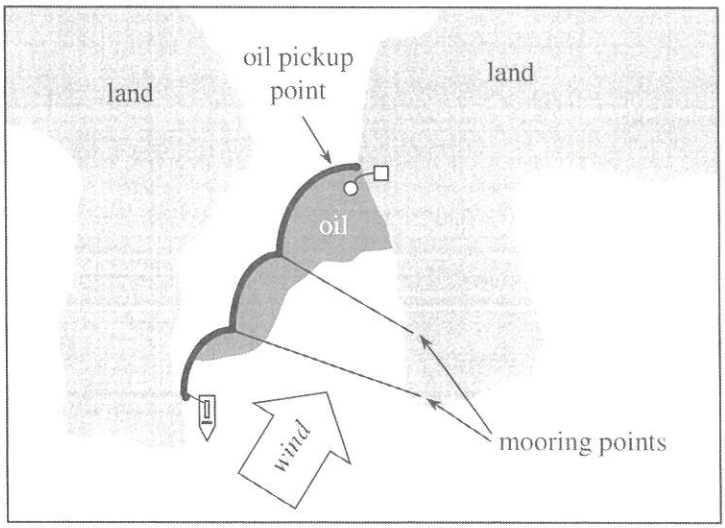

Figure 6-1 Exclusion Booming

Description	Boom is deployed across or around sensitive areas and anchored in place. Approaching oil is deflected or contained by boom.
Primary Uses	Across small bays, harbor entrances, inlets, river, and creek mouths with: • Currents <1 kt (0.5 m/s) • Breaking waves <1.5 ft (0.5 m) high
Environmental Effects	Minor disturbance to substrate at shoreline anchor points
Logistics	For calm weather, light boom: • Workboat plus crew • 6 anchors plus anchor line and buoys • 1 recovery unit (including skimmers, transfer and storage) For rough weather, heavy boom: • Workboat plus crew • 12 anchors plus anchor line and buoys (recovery not possible)

6.5.2 Diversion Booming

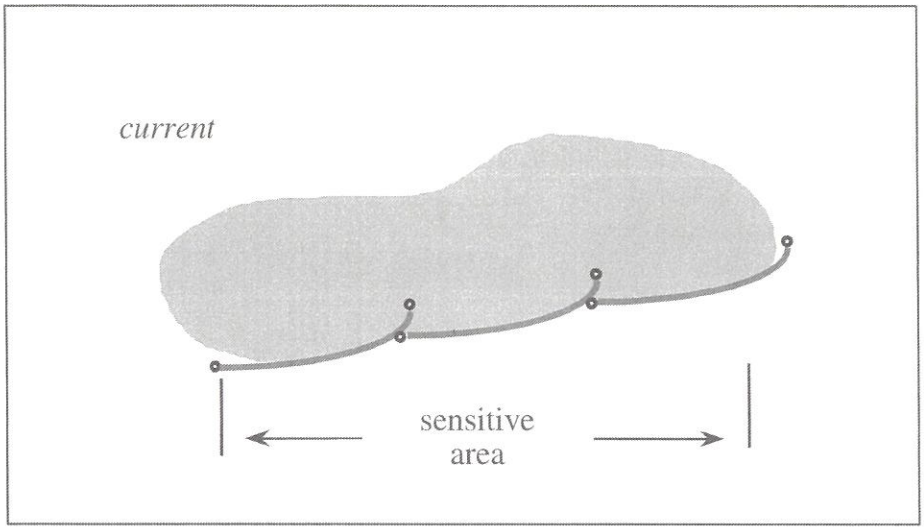

Figure 6-2 Diversion Booming

Description	Boom is deployed at an angle (see 5.4.1) to the approaching slick. Oil is diverted away from the sensitive area to a less sensitive location for recovery.
Primary Uses	• Inland streams with currents >1 kt (0.5 m/s) • Across small bays, harbor entrances, inlets, river and creek mouths with currents >1 kt (0.5 m/s) and breaking waves <1.5 ft (0.5 m) • On straight coastline areas to protect specific sites, where breaking waves <1.5 ft (0.5 m)
Environmental Effects	• Minor disturbance to substrate at shoreline anchor points • Diverted oil may cause heavy shoreline oil contamination downwind and down current.
Logistics	For single boom: • Workboat plus crew • 1 anchor plus anchor line For cascading boom: • Workboat plus crew • 6–9 anchors plus anchor line and buoys

6.5.3 River Booming

Various commercially available booms have been specially designed for operation in rivers. River booms include both top and bottom tension members that provide vertical stability and improved oil deflection capability in relatively high current, i.e., up to approximately 2–3 kts (1–1.5 m/s). Such booms can be effective in a river where there is uni-directional flow. In a large coastal river with reversing tides, repositioning a boom can be difficult and time-consuming.

When current speeds exceed 0.75 kt (0.4 m/s), it is necessary to angle the boom (including river booms) to reduce the current relative to the boom. Angling the boom also allows oil to be diverted to shore where it can be collected. (See also Section 5.4.1)

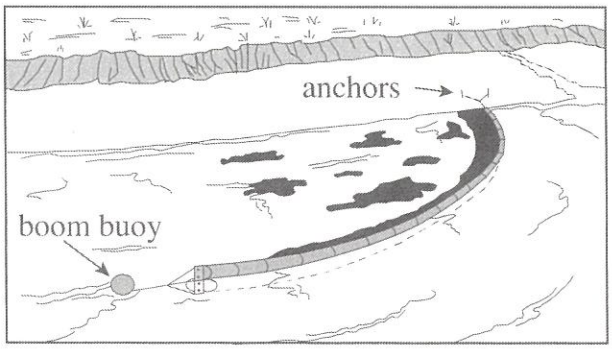

Figure 6-3 River Booming

6.5.4 Shore-Sealing Boom

Shore-sealing boom has water-filled lower and air-filled upper chambers that automatically adjust to changing water levels (Figure 6-4). The shore-end (stranded end) of the shore-sealing boom is fixed while the water-end (floating end) floats and is usually connected to a conventional boom.

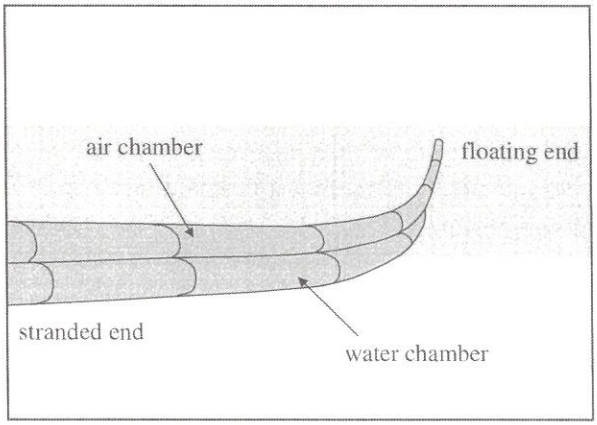

Figure 6-4 Shore-Sealing Boom

When deploying shore-sealing boom, the final position should be known before the boom is placed and anchored since redeployment is difficult, if not impossible, once the heavy water-filled chambers have settled on the shore. The water chambers of the boom must be fully filled or water will collect in the lower sections leaving the more highly elevated sections (toward the shore) only partially full or empty. However, on beaches with severe slope towards the water, shore-sealing booms can be damaged from stress on the waterside end connector if too much water is used.

Sites with boulders, sharp protrusions, riprap, or other features that will result in oil leaking under the boom when the tide changes should be avoided. Once deployed, shore-sealing booms require regular monitoring since currents, wind, and waves can move and/or twist them. Damage to fabric can result as a boom grounds and chafes in an intertidal zone.

6.5.5 Beach Berms

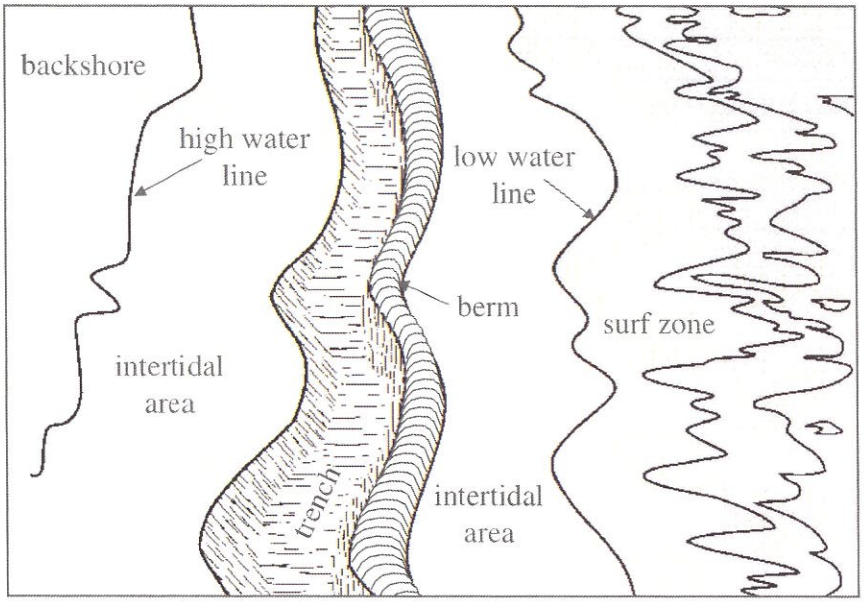

Figure 6-5 Beach Berm

Description	A dike or berm is constructed along the upper intertidal zone to prevent incoming tides from depositing oil onto back-shore areas.
Primary Uses	• Sandy or gravel beaches • Protects the upper intertidal and back-shore areas from contamination
Environmental Effects	Disturbs upper 2 ft (0.6 m) of beach sediments
Logistics	Beach can sustain motor traffic well • 1 motor grader Beach cannot sustain motor traffic well • 1–2 front-end loaders or bulldozers

6.5.6 *Berms, Dams, and Inverted Weir on Streams*

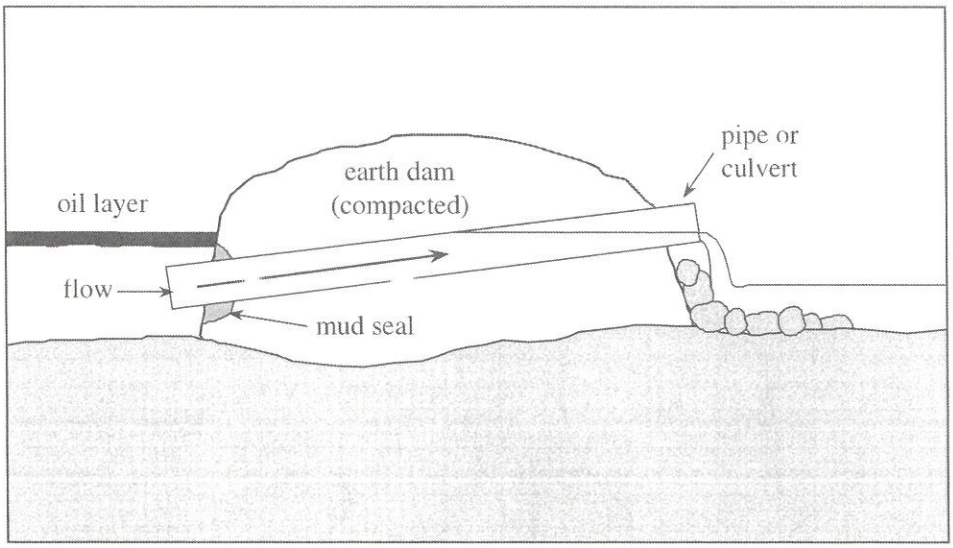

Figure 6-6 Inverted Weir

Description	Dams are constructed to either block flow completely or to block flow with a provision for underflow. Berms are constructed to control flow by diversion or underflow.
Primary Uses	Shallow streams or rivers where: • Booms are not available or cannot be deployed • Dams are part of the hydrological control system
Environmental Effects	• Local effects due to front-end loader • Blockage of fish movement
Logistics	For diversion berm or underflow dam: • Front-end loader or bulldozer • 3–6 short sections or 1 long section of boom • 1 skimmer, pump and tank For inverted weir: • Front-end loader or bulldozer • Discharge tube with or without valve • 1 skimmer, pump and tank

Traditionally, building an underflow dam or inverted weir would require larger mechanical equipment such as a front-end loader or bulldozer. An alternative would be to use a portable underflow device which replaces the dirt that would normally be required for narrow/small waterways to hold back the water and oil. Each device has numerous valves that can be opened and closed to regulate the amount of water passing underneath the dam. This device can be carried by two people which allows for greater flexibility in its use especially in areas that do not have sufficient access for large equipment.

6.5.7 Passive Sorbents

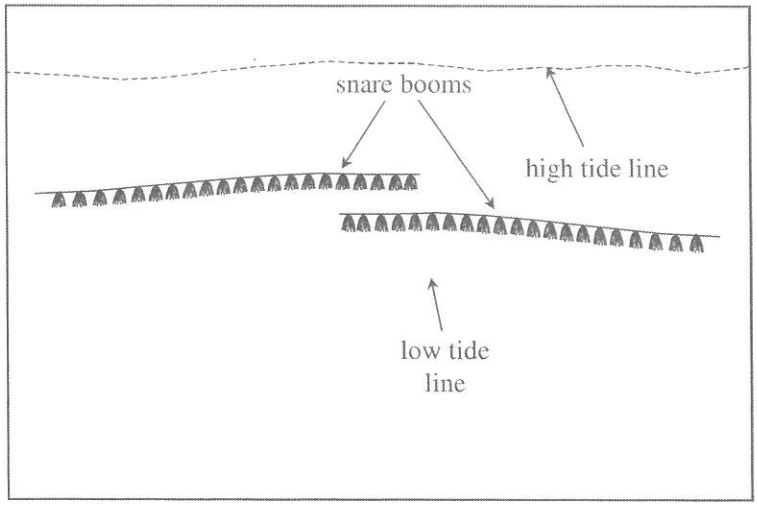

Figure 6-7 Passive Sorbents

Description	Snare booms (pom-poms on a rope) are positioned in the intertidal zone using stakes. See Section 10 for information on sorbents.
Primary Uses	Sand and gravel beaches and tidal flats
Environmental Effects	Minor disturbance to substrate
Logistics	For snare booms: • 2–5 snare booms • Wooden stakes • Disposal drums or large plastic bags

6.6 Material Take Off (MTO) List

There are a number of types of equipment required to successfully conduct shoreline protection.

Table 6-5 Material Take Off List for Shoreline Protection

Equipment	Use
Boom	Containing and deflecting oil
Portable Dam	Portable device to create underflow weir
Anchors	Anchoring boom
Rope	Towing, anchoring
Chain	Anchoring
Lights	Night-time illumination of boom
Sorbents	Beach protection, protection in ponds, streams
Vessels	Boom deployment, boom tendering
Motor grader	Constructing beach berms
Bulldozer and front end loader	Inverted weir construction
Skimmers	Oil collection
Containers, drums	Disposal of used sorbents, oiled debris
Pumps	Pumping oil

7 Dispersants

7

7.1 Introduction

Many international agencies and regulatory bodies around the world view dispersants as the most practical spill response option for offshore. In many cases, dispersing oil into the marine environment can result in the lowest environmental impact for offshore spill response. To assist in decision-making process on whether to use dispersants, a net environmental benefit analysis (NEBA) is performed. An advantage of dispersants is that they enhance the natural biodegradation process to speed removal of oil from the water, thereby reducing the potential of oil impacting shorelines, sensitive habitats, and wildlife found on or near the sea surface. This is the case for both surface application and sub-sea injection of dispersants.

Key aspects of dispersant use are listed below.

- The decision on whether or not to use dispersants should be made after considering the potential effects of dispersed oil versus undispersed slicks. This is because for large offshore spills, mechanical recovery may only encounter a small fraction of the oil leaving the majority of it untreated. The objective should be to minimize overall ecological impacts thereby maximizing net environmental benefit, i.e, through the use of NEBA.
    - Use of dispersants requires logistics planning including aircraft and/or vessels, application gear, re-supply of dispersants, refueling, sufficient personnel, protective equipment, and equipment calibration.
    - Many governments strictly regulate the use of dispersants. For example, in the United States, dispersants must be listed on the Environmental Protection Agency's (EPA) National Contingency Plan Product Schedule (the NCP list). In other countries, government authorities may approve dispersant use during a spill contingency plan approval process or when a spill occurs.
- For maximum effectiveness, dispersants should be applied as close to the source and as soon as possible after a spill. During the early stages of a spill, oil is un-weathered and less spread out, making it easier to target and disperse.
- Dispersants should be considered for use with other potential spill response methods and equipment, and not as a last resort.

The main goal of dispersant use is not to simply transfer oil into the water column but also to enhance its removal from the environment through the process of biodegradation. Along with this, the potential advantages of dispersants are as follows:

- Dispersants can be used over a wider range of environmental, meteorological, and oceanographic conditions than other response options for offshore spills. They can be applied in rough seas (up to 10 ft) and on thin oil slicks (<<1 mm).

- Dispersants can treat much more oil over time than other response options for offshore spills. They can be applied to surface slicks at high speeds by aircraft. In addition, aircraft allow rapid transit to a spill location and relocation to slicks separated by significant distances.
- Subsea injection of dispersants can proceed 24 hours per day and is less susceptible to any storm conditions at the sea surface.
- Dispersants can reverse, stop, or eliminate water-in-oil emulsion formation particularly when applied to low-viscosity oils. If emulsions form, the potential for oils to reach shorelines increases.
- Rapid dilution and biodegradation of dispersed oil occurs during both surface and subsea dispersant application. Dispersants accelerate the biodegradation of oil via the formation of very small dispersed oil droplets, which increase the surface area available to bacteria. Rapid dilution of dispersed oil ensures biological activity does not exhaust available nitrogen, phosphorous, and oxygen needed for biodegradation.
- Subsea injection of dispersant reduces the amount of oil rising to the sea surface and this in turn (a) reduces exposure of surface vessels and personnel to volatile components of the oil and (b) reduces the need for surface recovery using mechanical equipment, in situ burning, and surface dispersant operations. This reduces exposure of response personnel to accidents during these operations.

The potential disadvantages of dispersants are as follows:

- Dispersed oil, transferred into the water column, could potentially expose marine organisms which might not otherwise be exposed to oil. However, because dispersed oil rapidly dilutes, periods of exposure are short, and concentrations fall below toxicity thresholds within minutes to hours of initial dispersion.
- Dispersants are not effective on all types of oil. Higher viscosity oils, oils that have become more viscous, oils that have cooled below their pour point, and oils that have emulsified may be less dispersible. Some dispersants have been formulated to work on heavy and weathered oils.
- Although modern dispersant formulations exhibit low toxicity and are used in volumes that are a fraction of the spilled oil volume, they add chemicals to the marine environment. However, once in the environment, dispersants undergo the same dilution and biodegradation as the dispersed oil.
- Operationally, dispersant use on patchy slicks may be inefficient when applied by large fixed wing aircraft. A large, multi-engine aircraft such as a C-130 may have a swath width significantly greater than the width of slicks that form into windrows over time. In these cases, the advantages of aerial application may be lost as vessel-based application could be more suitable.

Potential advantages and disadvantages of dispersants are summarized in Table 7-1.

Table 7-1 Potential Advantages and Disadvantages of Dispersant Use

Advantages	Disadvantages
• Removing oil from the water surface keeps it from reaching shoreline	• May adversely affect some marine organisms that would not otherwise be exposed to oil
• Is often the quickest response method	• Not effective on all types of oil under all conditions
• Can be used in strong currents and higher sea states	• If dispersion is not achieved, may decrease the effectiveness of other method
• Reduces possibility of sea bird and marine mammal exposure	• Adds substances into the marine environment
• Inhibits formation of emulsions	• Limited time window for use
• Facilitate natural biodegradation	
• Dipersants lower the adhesive properties of oil	
Reference: *IMO/UNEP Guidelines on Oil Spill Dispersant Application*, 1995 edition, IMO, London, 1995.	

7.2 Suggested Dispersants

While the COREXIT™ products have been studied extensively and are present in a number of inventories around the world, other products are available as well. For example, Oil Spill Response Ltd (OSRL) is implementing a global stockpile of 5000 m^3 of three of the most common dispersants. These will be stored at various locations to enable prompt access to dispersant in the event of a release with a focus on a subsea intervention. In addition to COREXIT™ EC9500, Finasol OSR 52™ and Dasic Slickgone NS™ will also be available. Information concerning applicability, toxicity, and effectiveness should be obtained from the manufacturer.

7.3 Dispersant Use Near Sensitive Habitats

Dispersants can reduce the amount of oil reaching near shore and shoreline sensitive habitats such as:

- Mangroves
- Salt marshes
- Coral reefs
- Kelp beds

It is best to disperse oil some distance before it approaches important ecological habitats. For situations where this is not possible and with the agreement of the relevant government agencies, guidelines for using dispersants near specific ecological habitats are discussed below. In general, care should be taken to avoid excessive application.

7.3.1 Kelp Beds

Dispersant use is recommended for protecting kelp beds, which occur most often on rocky subtidal habitats. Dispersants should be used where there is sufficient water circulation and flushing for dilution.

7.3.2 Seagrass Beds

Dispersant application can protect seagrass beds in the intertidal zone. The use of dispersants over shallow, submerged seagrass beds or in areas of restricted flushing is generally not recommended, but should be weighed against the consequences of untreated oil stranding on shore.

7.3.3 Coral Reefs and Lagoons

Dispersant use should be considered in waters near coral reefs and lagoons to prevent oil from contacting the reefs. Applying dispersants to oil directly over shallow, submerged reefs is generally not recommended, particularly if the water exchange rate is low such as in lagoons and atolls.

7.3.4 Nearshore Sub-Tidal Zones

For nearshore zones of sandy and gravel/cobble beaches and for bay habitats, dispersant application is a possible option when there is sufficient water circulation and flushing capacity for dilution.

7.3.5 Tidal Flats

Dispersants should not be applied to oil that is stranded on exposed tidal flats. However, dispersant use can be considered in nearshore shallow waters after considering net environmental benefits. Limited biological impact to tidal flat sediments is expected because little dispersed oil is incorporated into the sediments.

7.3.6 Salt Marshes

Salt marshes can be protected either by applying dispersants offshore or to open water and channel areas in a marsh, but not to the marsh surface itself. If an oil slick is approaching a marsh, dispersants should be applied as the tide starts to rise, if possible. This approach will maximize dispersion of oil. Dispersants should not be used in marshes that cannot be flushed.

7.3.7 Mangroves

Dispersant use is a preferred technique for protecting mangroves because of the potential persistence and long term effects of oil on roots. If dispersed oil reaches a mangrove forest with a small tidal range, attempts should be made to flush it out as soon as practical.

7.3.8 Other Considerations—Marine Birds and Mammals

Dispersant use is recommended in offshore and coastal areas when this would prevent oiling of marine birds and mammals from contact with oil slicks. This is particularly true when large colonies of animals are engaged in nesting, rearing, feeding, and over-wintering activities near a shore. Direct spraying of dispersants on animals is to be avoided.

7.4 Dispersant Dosage

The conventional planning basis for dispersant dosage is 1 part to 20 parts of oil, also known as a dispersant to oil ratio (DOR) of 1:20. However, this does not take into account the wide range of properties found in both oil and dispersants which influence dispersant effectiveness. From a strategic point of view, less potent, lower cost dispersants may also be effective on oils that are easily dispersible at DORs of 1:20–30. Alternatively, lower dose rates of more potent dispersants could achieve the same goal, e.g., about 1:50–100 DORs. For oils of typical dispersibility, more robust products, such as Corexit™ EC9500 or comparable, would be used in the range of 1 part dispersant to 20–50 parts oil. For heavy oils or highly weathered

or emulsified oils, products specially formulated for heavy oils, such as Corexit™ EC9500 or similar products, may be required at levels as low as a 1:10 DOR to achieve effective dispersion. On lighter oils, dispersion may occur spontaneously or within a very short time after application. For the heavier oils, dispersion may not occur immediately and may in fact take as long as 30 minutes or more depending on wave activity, so longer term monitoring may be needed for the heavier oils to confirm effectiveness.

For typical slicks, an application rate for dispersant concentrates of between 2 and 10 US gallons per acre (19 to 94 liters per hectare) can be used. An application rate of 5 US gallons/acre (47 liters/hectare) is often used. On a volume-of-dispersant to volume-of-oil basis (i.e., the DOR), these application rates range from less than 1:100 to more than 1:10, depending on the thickness of the oil slick and its dispersibility. Two guidelines should then be followed:

- High application rates; e.g., 10 US gallons/acre (94 liters/hectare) and/or multiple pass applications are used for thicker layers of viscous oils.
- Lower rates are more applicable to thinner layers of lighter oils and to subsea injection.

The following formulas can help estimate the quantity of dispersant to apply:

D (dispersant dosage in US gal/acre) = 27,200 x t x R
P (pump rate in US gal/min) = 63.2 x N x S x t x R

where: t = average thickness of oil in inches
R = desired dispersant-to-oil volume ratio
N = speed of boat or aircraft in knots
S = swath width on the water surface in feet

1 US gal/acre = 9.353 liter/hectare
1 US gal/min = 0.0631 liters/sec

For example, at a:

speed = N = 140 knots (1 knot = 1.85 km/hr)
swath width = S = 150 ft (1 ft = 0.3048 m)
average oil thickness = t = 0.01 in. (1 in = 25.4 mm)
dispersant-to-oil ratio = R = 1:40

D (dispersant dosage) = 27,200 x 0.01 x 1/40 = 6.8 gal/acre
or approximately 64 liters/hectare

P (pump application rate) = 63.2 x 140 x 150 x 0.01 x 1/40 = 332 gal/min
or approximately 20.9 liters/sec

Swath width can be estimated or measured during tests. For vessel applications, to estimate a swath width for a spray boom system, multiply the width from the hull to the outermost spray impact on the water by two (2). Fire monitor swath width depends on the type of fire monitor and can be tested over land. For aircraft, the swath width estimate is 1.2 to 1.5 times the distance between terminal nozzles for operating at a 50 ft (15 m) to 75 ft (22.5 m) altitude. Altitude and winds affect swath width, and spotter aircraft guiding spraying operations should check these parameters.

7.5 Dispersant Application Techniques

Historically, there have been two basic methods used to apply dispersants:

- Vessel application
- Aerial application

In 2010, dispersants were injected at the source during an offshore well control event. Subsea use of dispersants provide an effective means of introducing dispersant very close to the source of a release, thereby offering the possibility of achieving very high encounter rates. This method was credited with keeping volatile fresh oil from the surface near where responders were attempting to control and contain a well blowout. This method reduced impacts to surface dwelling marine life and shorelines and minimized exposure of workers to volatile organic compounds. If a well control incident occurs in the future, subsea dispersant injection at the source should be considered.

The main goal of dispersant use is not to simply transfer oil into the water column but to enhance its removal from the environment through the process of biodegradation. Dispersant treatment of surface slicks should proceed as illustrated in Figure 7-1, taking into account the following considerations:

- Treating a spill with dispersants should prevent the intact slick from reaching a shoreline or sensitive area.
- Normally, treatment should begin at the outer edges of the thicker parts of the slick rather than through the middle or on very thin sheen surrounding a slick.
- If the slick is near shore, the preferred spray pattern is in swaths back and forth parallel to the shoreline.

While not shown in Figure 7-1, wind conditions generally dictate the spray pattern. The following rules of thumb should be considered:

- Boats may need to travel with the wind to avoid spray blowback onto the deck.
- Aircraft should spray while flying into the wind, though downwind application may be suitable for some wind conditions.
- Aircraft should avoid spraying into strong crosswinds which can carry dispersant off target.

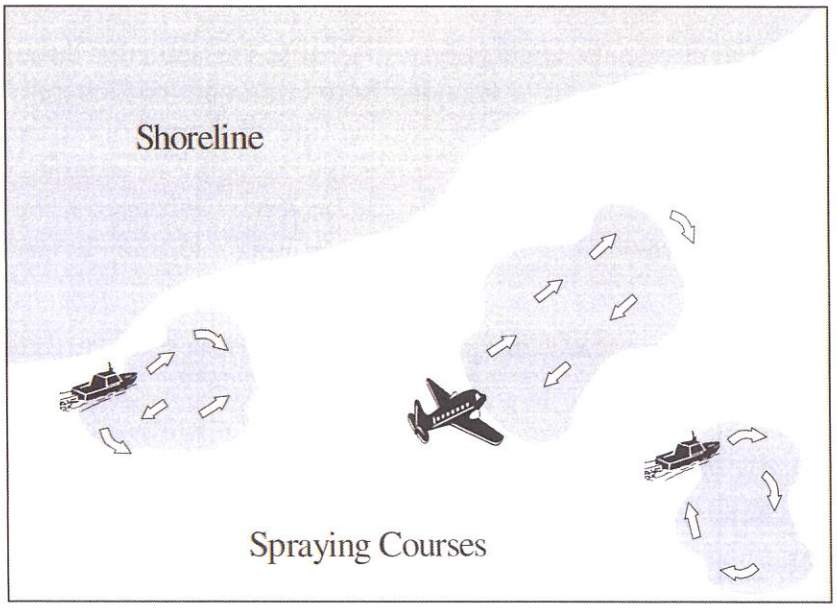

Figure 7-1 Dispersant Application

Dispersion of oil droplets into a water column is influenced by the amount of mixing energy. Dispersant application should proceed even if initial wind and sea conditions appear calm or if immediate dispersion of oil is not readily observed. Weather changes can generally be expected in marine environments (often very rapidly) and many dispersants tend to remain in an oil slick for some time after application. Further, low-energy seas make application of dispersant more efficient because slicks are easier to identify and treat.

The time taken to respond to a spill influences the effectiveness of a dispersant treatment. Over time, an oil slick weathers and becomes more viscous, especially if it incorporates droplets of water (emulsifies) and becomes a "mousse." The resulting increase in viscosity and water content makes chemical dispersion more difficult. The rate of weathering is primarily a function of oil type, slick thickness, sea state, and temperature. Treatment time can be significantly reduced by using large, multi-engine airplanes when operating over large distances.

7.5.1 Vessel Application Systems

Two systems for dispersant application from boats are spraying through a set of nozzles fixed on outboard arms or spraying from fire monitors. Generally, workboat systems are slow, have limited swath widths, and are used primarily for smaller spills close to land. In most cases, an airborne observer is useful to accurately guide the boat to thicker slicks. Treatment efficiency can be greatly enhanced if the vessels are re-supplied with dispersant and re-fueled at the treatment location to lessen delay in spray operations.

7.5.1.1 Vessels with Spray Arm Systems

- Spray arms with nozzles can be used to give a flat, uniform spray of droplets, not a fog or mist.
- Spray arms should be mounted as far forward as possible to minimize bow wave impacts.
- The added mechanical energy of a wake from a boat can enhance dispersion. Other dispersion-enhancing techniques that have been used and might be useful for some applications (e.g., nearshore and/or calm conditions) include the use of firehose water streams, other wakes produced by small boats, and towed wooden panels ("breaker boards").

Dispersant spray systems for boats are available from various manufacturers. Many differ in design, capability, versatility, size, weight, ease of handling, and control of dosage. Some equipment is fabricated for specially designed vessels.

Spray arm systems for boats should:

- Be easily transported and loaded.
- Preferably be light in weight, yet rugged.
- Be quickly and easily installed.
- Preferably have a pump as an integral part of the system and have a pressure gauge at the main pump outlet.
- Be versatile, i.e., easily adapted for different nozzles, for a range of dosages and use situations, or for placement on other vessels.
- Be equipped with nozzles that will produce a flat spray of droplets (not mist or fog) striking the water in a line perpendicular to the direction of travel of the vessel.
- Have features that allow variation/regulation/measurement of dispersant flow and water flow (if dilution is used).
- Be calibrated (using water) under potential conditions (e.g., variations in boat speed, water/dispersant flow rates, swath width sprayed) and have calibration charts prepared for use during spill response.

7.5.1.2 Vessels with Fire Monitors or Other Single Point Spray Systems

Fire monitors or similar hose-like devices on vessels are effective dispersant application systems provided that proper nozzles, pressures, flow rates, dispersant metering, and vessel operation practices are employed.

Two fire monitor application systems are recommended. The most flexible and easiest to operate is a package that uses positive pressure injection of dispersant into the water flow. This system relies on external pressure and metering systems to deliver a specific quantity of dispersant to the pressurized water stream. The second system uses eductors to draw dispersant into the water flow. The main advantage of an eductor system is its simplicity. The main disadvantages are poor control available on the amount of dispersant being drawn into the water stream and inflexibility in dealing with wide ranges of flows and pressures. Both systems rely on water-diluted application of the dispersant with a typical concentration of dispersant in the water stream of 5 to 10%.

Fire monitor dispersant application systems are capable of treating up to four times as much area as spray arm system. This is primarily due to their greater swath width, faster vessel speed, and the pitch and roll of a vessel, which do not affect the system to the same degree as the spray arm system. Fire monitor dispersant application systems are rugged for open water applications. Furthermore, vessels equipped with a fire monitor application system can perform other operations when not responding to spills.

When a fire monitor or fire hose is used, then raising the outlet nozzle to about 32° above horizontal will generally give the greatest reach. Mounting a "break-up screen" (coarse 4-mesh) over the end of the nozzle will spread the spray over a greater area. At the water surface, droplets should resemble a fine rain, not a fog or mist. If the fire monitor has an adjustable nozzle, the optimum adjustment is generally just short of the "straight-stream" position.

7.5.2 Aircraft Application

There are several factors to consider when applying dispersants from aircraft:

- As with boats, an important concern is a properly designed system of tanks, pumps, and nozzles. Dispersant droplet size in the range of 0.01-0.03 in (300-700 micron) is typically optimal for effective application.
- Some large helicopters and airplanes can treat more area per day than boats, especially when slicks are offshore or in remote areas.
- Helicopters and small fixed-wing aircraft are more appropriate for small spills or fragmented slicks close to shore.
- Large, multi-engine airplanes such as L-100/C-130 Hercules, DC-6, or DC-4 or DC-3 aircraft are appropriate for large spills, particularly in relatively open waters or far from shore.
- Jet aircraft, e.g., Boeing 727s and 737s, are being considered and developed as dispersant platforms (Figure 7-2). They offer much quicker transit to and from an oil spill, potentially increasing the surface slick size that may be treated effectively.

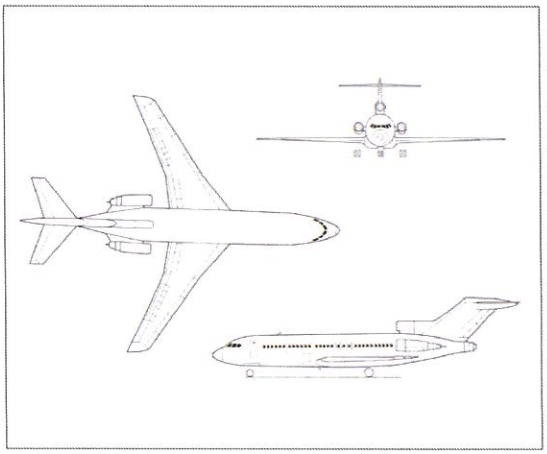

Figure 7-2 An example of the jet aircraft developed as a dispersant application platform

The characteristics of typical aircraft suitable for aerial dispersant spraying are given in Table 7-2. The dispersant delivery capabilities in a 10-hour day of various types of aircraft are shown in Table 7-3.

	5,000	170	129	5	2	135	25,000

Conversions: 1 gal = 3.785 liter
1 mile = 1.6 km

The number of nozzles used depends on the flow rates employed. The differential velocity between the aircraft speed and the exit velocity of a dispersant fluid should be less than about 210 ft/sec (64 m/sec) for best depositional efficiency.

$$V_d = V_a - V_f$$

$$V_f \text{ (ft/sec)} = \frac{0.41 \times \text{total gpm / number of nozzles}}{d^2}$$

where:

V_d = differential velocity, ft/sec
V_a = aircraft ground speed, ft/sec
V_f = fluid exit velocity, ft/sec
d = nozzle diameter, in

Smaller planes and helicopters, such as those used for agricultural spraying and forest fire fighting, have been and can be adapted for dispersant spraying. Although this would not serve for all operating speeds or pump rates, as a general guide, these small aircraft should not use nozzles with external orifice diameters smaller than 0.156 in (4 mm). Preferably, they should have no more than a total of 30 to 35 operating nozzles per plane.

The mechanical shear rate of a nozzle should be as low as possible and preferably less than 10,000 sec-1 to avoid generation of small droplets that may result in misting. The formula noted below can be used to calculate mechanical shear.

Shear Rate (sec-1) = $3.9\ q/d^3$

where:

q = flow rate (gal/min) *note*: if flow is given in ml/sec, use $q = \frac{\text{ml/sec}}{63.08}$

d = orifice diameter (in)

Dispersant viscosity can affect flow rate and spray patterns and should be checked at the application temperature. For satisfactory aerial spraying of dispersants, dispersant viscosity at application conditions should be taken into account, as shown in Table 7-4.

Table 7-4 Dispersant Fluid Viscosity and Application Conditions

Dispersant Fluid Viscosity (at application temperature)	Application Condition
≥ 60 centiStokes (cSt)	• Best for aerial application
30–60 cSt	• Adequate if aircraft's ground speed is less than 100 mph (160 km/hr) and altitude is not over 30 ft (10 m)
< 30 cSt	• Not satisfactory for aerial application since a fluid stream is easily shattered by air shear • Produces extremely small size droplets, which are subject to excessive drift

7.6 Material Take Off (MTO) List

There are a number of types of equipment required to successfully apply dispersants.

Table 7-5 Material Take Off List for Dispersants

Equipment	Use
Dispersant	Oil dispersion
Tanks	Temporary storage of dispersants
Pumps	Transfer of water/dispersant
Boats/Vessels	Dispersant application platform
Fixed-wing aircraft	Dispersant application platform, directing and monitoring operations (spotter aircraft)
Helicopters	Dispersant application platform
Fuel	Fueling aircraft
Spray equipment	Dispersant application
Tools	Setting up spraying, adjusting and repairing connections
Radios	Communication among vessels/aircraft
GPS	Positioning aircraft and vessels, documenting operations

7

8 In-Situ Burning

8

8.1 Introduction

In-situ burning (burning oil in place) can quickly eliminate large quantities of spilled oil. In-situ burning removes oil from a surface by combustion of hydrocarbon vapors and their conversion into predominantly CO_2 and water which are released to the atmosphere. There are often situations where burning may provide the only means of quickly and safely eliminating large amounts of oil. The objective is to select the optimal equipment and application techniques that will result in the least overall environmental impact.

Burning small spills has been routinely conducted for the following purposes:

- To quickly remove oil, so that it does not spread over larger areas or to sensitive sites.
- To reduce the generation of oily wastes, especially where transportation or disposal options are limited.
- As a final removal technique, when other methods begin to lose effectiveness or are judged to be too intrusive.

8.1.1 Regulatory Approval

In the United States, many coastal areas have been pre-approved for in-situ burning under certain conditions. This pre-approval process is an important step, and it will expedite the formal process of obtaining final approval to burn in the event of an oil spill. In contrast, many nations have yet to provide in-situ burning guidance or regulations.

Burning is valued where there are hard surfaces (manmade, snow, ice), ditches or trenches to collect spilled oil from porous soils, shallow water, soft substrates, or the remoteness of the location limits access to the spill site. The following conditions favorable for burning have been identified:

- Spills of fresh crude oil or light, refined products either on land, in freshwater, lakes, ponds, and streams, in marshes, or in offshore marine environments
- Winds <~20 miles/hour offshore and <12 miles/hour onshore (34 km/hr and 19 km/hr, respectively) for ignition
- Remote or sparsely populated sites
- Mostly herbaceous vegetation (fields, crop land, marshes)
- Dormant vegetation (not in active growing season)
- Unvegetated or poorly vegetated areas (dirt roads, ditches, dry streambeds)

- In wetlands with a water layer covering soil substrate, or water-saturated soils
- Where snow and ice provide natural containment and substrate protection
- In offshore environments

Advantages and disadvantages of In-Situ Burning are summarized in Table 8-1.

Table 8-1 Advantages and Disadvantages of In-Situ Burning

Advantages	Disadvantages
• Can quickly remove large amounts of oil	• Ignition of weathered or emulsified oil can be difficult
• Can lessen recovery time and disposal chain for oily wastes	• Generates smoke and soot
• Once ignited, most oils will burn	• Has inherent but manageable safety risks
• Can be used in any water environment (marine, estuarine, freshwater)	• Some residues can sink
• Can be carried out at night	• Fire booms required for burning of freshwater and marine oil spills are large pieces of equipment that are a challenge to rapidly transport

8.2 Basics of In-Situ Burning

8.2.1 Basic Requirements of In-situ Burning

- Oil layer thickness must be approximately 2 to 3 mm (0.08–0.12 in) or more to generate burnable concentrations of hydrocarbon vapors to sustain combustion.
- Oil must be relatively fresh and not contain too much water (i.e., emulsified) to generate burnable concentrations of hydrocarbon vapors to sustain combustion.
- Quantity of spilled oil should be sufficient to generate a supply of hydrocarbon vapors to sustain a burn, once it is ignited.

- A fire-resistant boom is generally used on open water to hold the oil in thicker slicks to help sustain a burn.
- An igniter is used to heat spilled oil to release more hydrocarbon vapors and then to ignite them to start a burn.
- For oils which are difficult to burn, an accelerant or promoter (e.g., lighter, highly evaporative oil) can be applied to assist with ignition.

For burns on water, the boom holding capacity can be estimated from Figure 8-1. Mouth openings of 0.3 total boom length (0.3 x L) and 0.6 total boom length (0.6 x L) are shown. The 0.3 x L configuration is recommended since it requires lower boom tension and is more easily controlled.

8.2.2 Efficiency of In-situ Burning

Burn efficiency depends on the original oil thickness, its weathering state or burnability, and, in a continuously fed oil fire, how well burn areas are maintained throughout the burn process.

- Thick oil layers (13 mm or more) normally burn with a thickness reduction rate of 2.54 mm /minute (i.e., about 2.5 liters per minute per square meter of burn area or 0.7 gallons / minute per 10 ft^2).
- With combustion normally taking place until the final thickness is approximately 1 mm, burn efficiencies in excess of 90% can be achieved. Figure 8-2 can be used to determine the area required to consume various amounts of encountered oil.

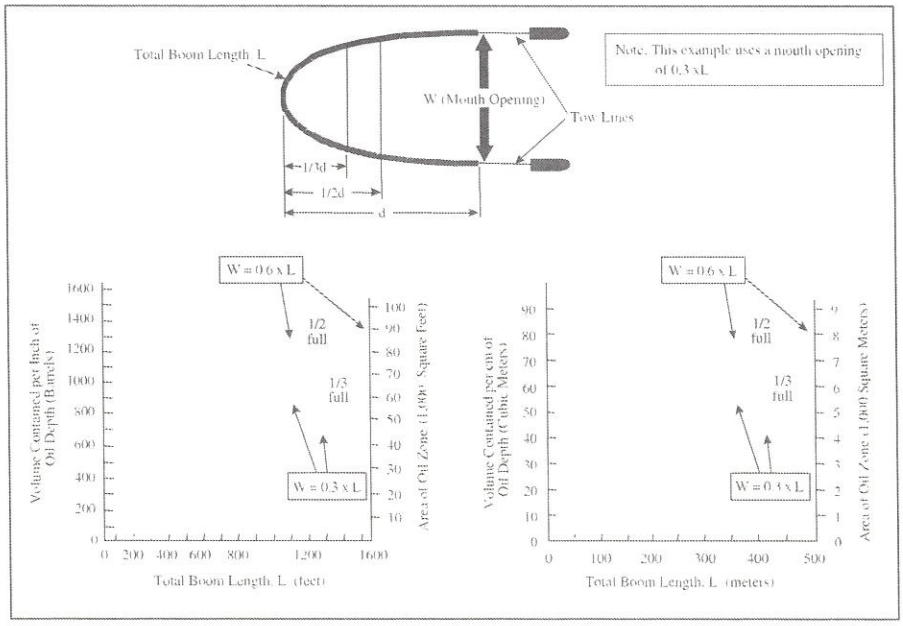

Figure 8-1 Estimating Boom Holding Capacity

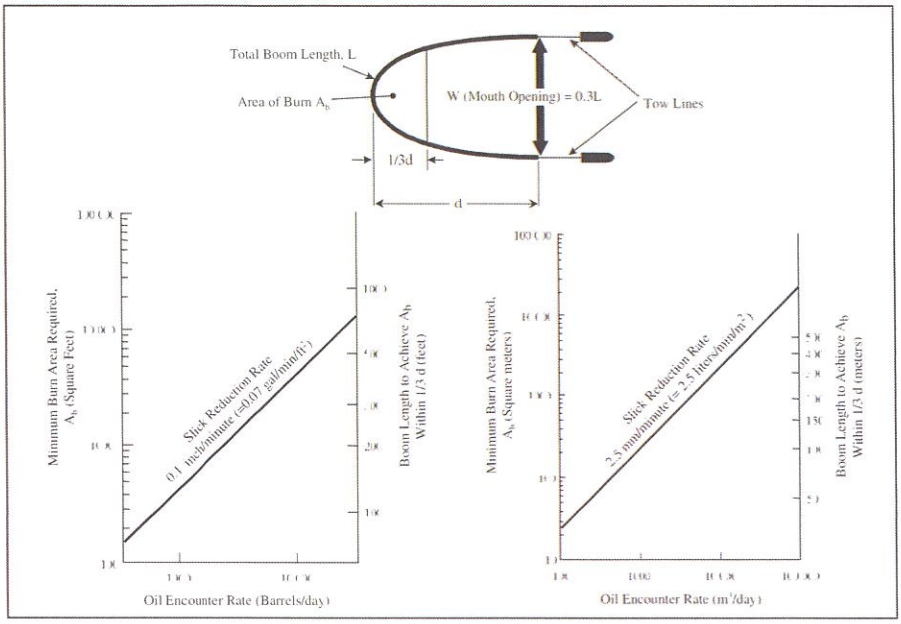

Figure 8-2 Estimating Area Required for Various Oil Encounter Rates

8

8.2.3 On-Water Conditions and Weathering

Oil slicks thicker than 2 to 3 mm (0.08–0.12 inches) on water can be ignited easily under light wind and wave conditions. Ignition and burning of floating oil may still be possible in winds up to approximately 21 mph (18 kts or 34 km/hr) and/or in waves as high as 1–1.5 m (3–5 ft). Ignition and sustained combustion may occur under much more severe conditions if the spilled oil is fresh and unemulsified.

Ignition of floating oil is affected by evaporative losses, dispersion (chemical or natural), and water-in-oil emulsions. Water content of 15 to 25% makes ignition difficult for some oils. For most oils, a 50 to 70% water content makes ignition almost impossible unless very large ignition areas, igniters, and/or other fire promoters are used. Minimum ignitable thicknesses include:

- Fresh oil: 1 mm
- Aged un-emulsified crude and diesel: 2–5 mm
- IFO 380, Resid, Bunker C: 10 mm

8.2.4 Recovery of Residue

Most crude oils will leave an unburnable residue after burning. This residue primarily consists of the non-volatile components in the oil: mostly inert tars and asphaltenes. Unburned oil residue may reach a thickness of several centimeters and be sufficiently viscous to be picked up with equipment such as boat hooks, screened rakes, or pitch

forks. Fishing nets with relatively small openings (2.5 cm [1 in] or smaller) would be adequate to corral and recover the buoyant residue from on-water burns. The residue, and most likely the fishing nets, could then be placed in plastic-lined containers or in drums for disposal.

8.3 Burning Equipment

The main equipment required for in-situ burning on land, snow, or ice is an igniter. The main equipment required for in-situ burning on water consists of fire-resistant boom, igniters, and vessels to pull the boom. Similar to conventional boom, fire-resistant boom requires ancillary equipment such as towing lines, bridles, buoys, and anchors. For pressure-inflatable boom, an air compressor is needed. Fire-resistant boom and igniters specific to in-situ burning are discussed in this section. Chemical herders could be used to help with on water burns.

8.3.1 Fire-Resistant Boom

Fire-resistant boom made of rugged material, such as stainless steel, can survive repeated burning for long periods. However, it is heavy and difficult to handle. Other types of less rugged boom incorporate fire-resistant, mineral-based fabric and ceramics in their structure. This less rugged boom is lighter and easier to deploy, position, and retrieve, but it may not be as capable of long-term deployment or tolerate long-term exposure to fire. The latest design of fire boom uses fire resistant fabric over a water-cooled interior, making the boom more durable and therefore reusable. In some instances, especially where the length of a fire boom is limited, conventional boom can be used as extenders on either end of a fire boom.

8.3.2 Igniters

A good ignition system has the following features:

- It produces a reliable source of heat that causes rapid vaporization of a surrounding oil slick without forcing the oil away from the igniter.
- It is safe to operate, simple in design, easy to use, has minimal storage and transportation requirements, and has a long shelf life.

For safety reasons, aircraft pilots generally prefer to work with ignition systems that do not involve lighting fuses within aircraft and releasing an igniter by hand from an open window or door.

Two types of ignition systems are commercially available: igniters for use from land or on a vessel and igniters used from helicopters. The two types are listed in Table 8-2.

Table 8-2 Igniters

Deployment	Igniter
Surface (including vessels)	• Propane or butane torch • Drip torch • Flare • Gelled fuel in hand-held container • Plastic Sphere Dispenser (PSD) • Terra torch
Aerial	• Helicopter-slung gelled fuel, contained in a remote controlled torch • Plastic Sphere Dispenser (PSD) (for on-land spills)

8.3.3 Chemical Herders

Chemical herders can be used to aid in-situ burning without booms. They are composed of surfactants dissolved in one or more solvents. Herders sprayed onto water surrounding an oil slick cause formation of a layer of surfactants on the water surface. When the surfactant layer reaches the edge of a thin oil slick it changes the balance of interfacial forces acting on the slick edge causing contraction of the oil into a thicker layer. Herders do not require a boundary to "push against" and work even in open (boundary-free) water. Herding agents applied around the perimeter of an oil slick can keep slicks from spreading and cause thin slicks to "herd" into thicker slicks. This action can keep slicks from spreading too thin to burn and can thicken slicks that are already too thin.

Herders have been approved for listing on the United States National Contingency Plan Product Schedule. Commercial quantities of herder, and a herder delivery system capable of being mounted in the cabin of a helicopter are available.

Herders are an important advance for in-situ burning because they can be deployed from a helicopter. This same helicopter can also carry ignition devices. Figure 8-3 shows a helicopter with a heli-torch ignition system. The drawing shows herder already sprayed around the perimeter of the slick.

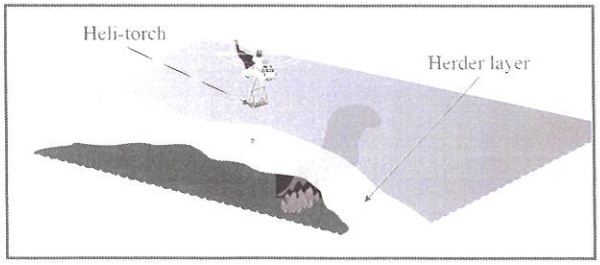

Figure 8-3 Conceptual drawing showing a helicopter herder – ISB system

8.4 Burning Operations

In-situ burning can be conducted on shorelines, inshore areas like wetlands or marshes, upland areas like fields and open terrain, on snow and ice, and in some forested areas if there is sufficient fire control. Until recently, most burn have been conducted in inland or upland areas.

8.4.1 Inland or Upland Burning

The following operational and post-burn guidelines need to be considered for inland or upland burns:

- Regulatory approvals.
- A means of fire control.
- Physical disturbance of the vegetation and substrate should be avoided.
- When oil does not ignite readily, an accelerant, e.g., diesel, may be needed.
- A crust or residue (which may hinder revegetation) may remain after incomplete combustion of spills on land, and may need to be cracked or removed.

The U.S. Department of Agriculture (USDA) Forest Service maintains a Fire Effects Information System. This database can be used to review information on local ecology and effects of fire on specific plant species.

- Erosion may be a problem in burned areas if plant cover is greatly reduced.
- Vegetation in, and adjacent to, a burn site can be affected by burning, including short or long term changes in the plant community.
- Burning can severely affect organic soils, such as peat, unless they are saturated.

Table 8-3 Inland and Upland Burning

Description

Oil is removed from a shoreline, ice / snow or soil surface by burning.

Application

- Use on any substrate or vegetation, except mangroves, where oil volume and properties will sustain combustion.
- Ignite the downwind end of oiled area and burn upwind.
- Use also on large pools of oil and on oily debris, e.g., logs.

Possible Adverse Effects

- Can result in mortality of surface organisms in a burn area.
- Can cause erosion if root systems are damaged; also may result in localized and temporary air pollution.
- Heating can reduce oil viscosity resulting in deeper oil penetration into a porous soil/beach, depending on their saturation.
- Generates black smoke and should not be used near population centers.

Primary Equipment	Type
Ignition Source	• Plastic Sphere Dispenser (PSD) • Helitorch • Drip Torch • Terratorch • Flares
Fire-fighting equipment	• Small fire trucks • Portable fire pumps with nozzles
Consumables	**Type**
Ignition agents	• Gelled gasoline • Diesel fuel • Flammable materials (rags soaked in diesel fuel, wood chips, dried brush, etc.) • Plastic spheres filled with potassium permanganate
Personnel	**Treatment Rate**
2–3 workers to ignite and control fire	See Section 8.2.2 burning rates
1 foreman for every 10 workers	
Access	
Foot path, roadways, shallow craft or helicopter	

8.4.2 Burning on Water

To conduct in-situ burning operations on water using booms, two vessels are generally needed to tow fire-resistant boom (Figure 8-4). One or two other vessels are needed for logistic support, such as transfer of personnel and recovery of residues. For larger spills, a spotter airplane should be used to assist in locating oil slicks, directing boom operations, and safety surveillance. Furthermore, it is strongly recommended that firefighting vessels be on site in case of any secondary fires.

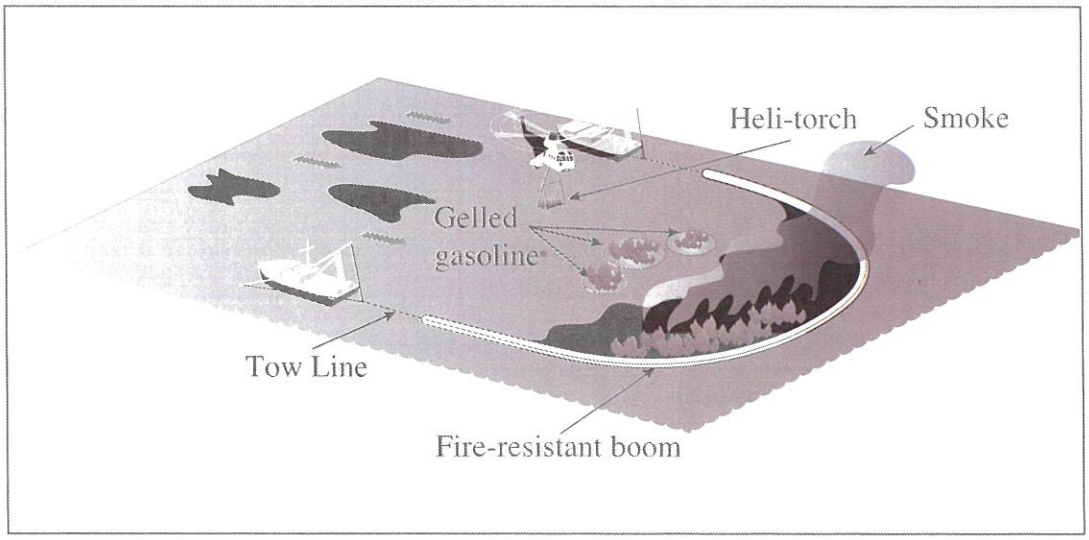

Figure 8-4 Typical In-Situ Burning Operation on Water

The transport and deployment of fire containment booms is not appreciably different from standard containment booms. Some fire booms are stored on reels, and the booms are deployed from, and retrieved back to, these reels. As long as the reels are properly sized, these booms can be transported in a variety of aircraft.

Other fire booms are stored in cradles that are lowered into the water during deployment to allow the boom to be towed out of the cradles. Fire boom is considerably heavier than most booms and is consequently more difficult to handle out of the water. The cradles do not fit in many types of aircraft, and the boom may have to be repackaged for air transport.

Any one of these booms could be damaged during burn operations, and retrieval could become difficult. Oil can penetrate deeply and soak the interior of the booms, and retrieval to the decks of vessels can be quite messy. While fire boom retrieval may be difficult, it must be compared to the difficulty of handling skimmers, transfer hoses, and storage containers during traditional oil recovery operations using mechanical devices.

Table 8-4 Burning On Water

Description

Oil is removed from the water's surface by burning.

Application

- Use on open water where oil volume and properties will sustain combustion.
- Boom oil to make it thick enough to burn.
- Ignite the downwind end of oiled area and burn upwind.

Possible Adverse Effects

- Generates burn residue that has the potential to harm benthic organisms if not collected
- Generates black smoke and should not be used near population centers.

Primary Equipment	Type
Ignition Source	• Marine flares • Helitorch
Fire Resistant Boom	
Vessels	• 2 for towing fire resistant boom • 1-2 small craft for ignition control
Consumables	**Type**
Ignition agents	• Gelled gasoline • Diesel fuel • Flares
Fire Resistant Boom	
Personnel	**Treatment Rate**
2–3 workers to ignite fire 2 crews for vessels pulling fire resistant boom	See Section 8.2.2 burning rates

8.4.3 Burning and Wind

Wind direction and strength (speed) each have an influence on the conduct of burn operations, whether on land or on water. Wind conditions and forecasts should be studied prior to burn operations.

Burning is most often planned with regard to wind direction for better fire control. Igniting a burn at an up-wind location provides added, natural fire control because the spread of flames and heat must overcome the contrary direction of the wind (Figure 8-5).

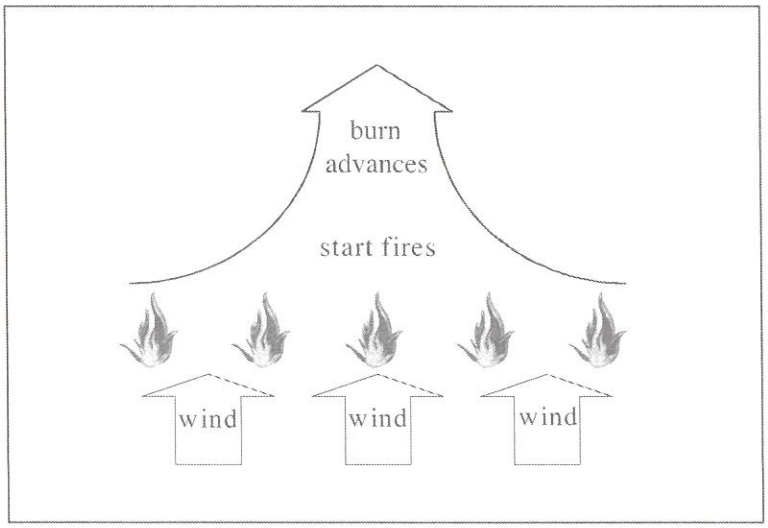

Figure 8-5 Initiating an In-Situ Burn

Wind strength can have a limiting influence on ignition. Since it is the hydrocarbon vapors evaporating from an oil slick which burn, those vapors must first collect in sufficient concentration to ignite. Winds tend to disperse vapors. A basic rule of thumb is that vapor concentrations cannot be maintained at wind speeds of > 35 knots (40 mph).

Once a burn is ignited for spills on water, there can be instances of induced winds created by the rising combustion plume from a larger burn. These winds can have a positive effect on total oil removals by drawing surrounding oil to a burn site for combustion.

8.5 Material Take Off (MTO) List

Various types of equipment are required to successfully ignite and burn oil, as listed in Table 8-5.

Table 8-5 Material Take Off List for In-Situ Burning

Equipment	Use
Fire-resistant boom	Slick containment
Rope	Towing
Cable	Towing
Conventional boom	Slick containment
Herder	Slick containment
Vessels	Ignition, boom deployment, fire-fighting
Helitorch	Ignition
Plastic Sphere Dispenser	Ignition
Hand-held igniters	Ignition
Gelled fuel/burning agents	Ignition
Vessels	Ignition, boom deployment
Fixed wing aircraft	Slick spotting, monitoring
Helicopters	Monitoring and slick ignition
Tools	Setting up igniter, booms; also for repairs
Radios	Communication among vessels/aircraft
Air monitors	Air quality sampling
Still/video cameras	Documentation
GPS	Positioning, documentation of operations

9 Skimmers

9.1 Introduction

Skimmers are mechanical devices that physically remove free or contained oil from the surface of water. There are many different types of skimmers but they can be grouped into four categories based on oil recovery principles. Each category contains various skimmer types distinguished by their oil collection mechanisms (Table 9-1) as well as other factors.

Manufacturers frequently offer several sizes or models of the same basic skimmer type and, in many cases, have updated older models with newer versions. For any given skimmer type, numerous manufacturers produce similar devices, each with its own specific design. Detailed performance and operational information are presented in Section 9.3 based on many decades of oil industry experience. However, this information is provided for background and general guidance only. The best source of data and information about a specific skimmer is the manufacturer. In a spill response, people use whatever skimmers are readily available so the information presented here is more useful for the selection and purchase of skimmers in advance of any response emergency. For responding in cold conditions, some skimmers can be fitted with a steam heating system to melt snow and ice in contact with the skimmer and to warm recovered oil for ease of pumping.

Consider each skimmer based on its own merits and the anticipated spill conditions.

Table 9-1 Skimmer Types

Skimmer Category	Examples
Weir skimmers	Simple, self-leveling, integral screw auger, advancing, and boom/weir systems
Oleophilic surface skimmers	Drum, grooved drum/disc, disc, fabric-coated drum/disc, rope mop, sorbent lifting belt, and brush
Hydrodynamic skimmers	Water jet, submersion plane/belt, and rotating vane
Other devices	Paddle belt, trawl/boom, vacuum skimmers

The advantages and disadvantages of mechanical skimmers are listed in Table 9-2.

Table 9-2 Advantages and Disadvantages of Skimmers

Advantages	Disadvantages
• Physically remove oil from the aquatic environment	• Relatively low encounter and recovery rates, especially in thin slicks
• Available in practically every equipment stockpile	• The use in high seas and high currents is often not practical
• Can be used in any water environment (bays, inlets, etc.)	• Considerable ancillary and supporting equipment must be planned for
• Their use is widely accepted	• Can be clogged by debris and ice

9.2 Skimmer Selection Matrix

Skimmer performance can be rated in three ranges of oil viscosity (Figure 9-1).

Figure 9-1 Oil Viscosity Ranges

Three sea states are considered in this section (Table 9-3).

Table 9-3 Sea States

Operating Environment	Significant Wave Height feet (m)	Wind Speed knots (m/s)
Calm water	<1 (< 0.3)	< 6 (< 3)
Protected water	<3 (< 1)	<16 (< 8)
Open water	<6 (< 2)	<21 (<10)

Table 9-4 is a simple matrix that can be used to select a skimmer best suited for a particular cleanup need. The expected performance of 17 generic types of skimmers is rated according to 12 performance criteria.

Table 9-4 Skimmer Selection Matrix

		Skimmer Type																
		Weir Skimmers					Oleophilic Skimmers								Hydro-dynamic Skimmers			*
		Simple Weir	Self-Leveling Weir	Weir with Integral Screw Auger	Advancing Weir	Weir Boom	Drum	Disc	Grooved Drum/Disc	Fabric-Coated Drum/Disc	Rope Mop	Zero Relative Velocity Rope Mop	Sorbent Lifting Belt	Brush	Water Jet	Submersion Plane/Belt	Rotating Vane	Paddle Belt

Available with Storage					✔	✔	✔	✔	✔	✔		✔	✔	✔	✔	✔		✔

Legend ○ Good ◑ Fair ● Poor ✔ = Yes

* Other Devices

** Oil/Water Pickup % = % Oil in Recovered Product

The parameters rated in the Skimmer Selection Matrix (Table 9-4) should be considered together with other aspects when assessing a skimmer. The ratings of some criteria are independent of the size of a skimmer while the ratings of other criteria are directly proportional to skimmer size. For example, oleophilic discs operate poorly in debris but have high recovery efficiencies (low water pickup) regardless of disc or skimmer size. Recovery rate and suitability for use in open water, however, strongly depend on the size of a skimmer. A "good" rating, in any case, means that a commercial version of that skimmer type is available that will deliver the indicated performance. A more detailed assessment of each skimmer type is provided in Sections 9.3.1 to 9.3.17.

Users should be aware that the nominal oil recovery rate of a skimmer is seldom achieved due to difficulties associated with changing conditions, e.g., diminishing layers of oil.

The availability of three additional skimmer features is indicated in the last three rows of the Matrix:

- Deployable from an existing workboat as a Vessel of Opportunity Skimming System (VOSS)
- Can be used as an advancing skimmer (some models are designed to be towed through the water)
- Available with storage (some models have integral storage)

Stationary skimmers, i.e., those that are not towed or self-propelled, are generally used inside containment booms where the oil layer thickness can be maximized.

The following guidelines should facilitate skimmer operation:

- Skimmers that incorporate relatively complex mechanical systems, e.g., those with rotating or moving oil pickup mechanisms, require operator experience for effective/efficient use.
- Skimmers used with centrifugal pumps can mix oil and water to form emulsions that cannot be readily separated. This adds to the volume of liquid that must be transported.
- Skimmers with screw auger pumps can be used to recover highly viscous oils and debris.
- Weir skimmers tend to collect a substantial amount of water, especially when operated in waves.
- Weir skimmers work best in thick slicks in calm water.
- All skimmers will pick up some water, and oil/water separation of the recovered liquid may be required.
- Safe and effective operations at night will require floodlights that are positioned so that the work area is properly illuminated.

To use the Skimmer Selection Matrix, follow these steps:

Step 1 Identify the environment in which a skimmer will be operated. Usually, only one environment will apply. Select those skimmers that perform well in the given environment (good rating, or ◯).

Step 2 Identify the type of oil that a skimmer will be required to recover. From the skimmers identified in Step 1, select those that have a good rating (◯) for the oil viscosity of concern.

Step 3 Choose the most important, applicable selection criteria and list these in order of priority. From the skimmers that have "passed" Steps 1 and 2, choose those with the highest rankings of the most important criteria.

Having identified one or more suitable skimmer types, consult the *World Catalog of Spill Response Products, the International Oil Spill Control Directory*, or other similar publications, to identify potential suppliers and to compare equipment specifications.

9.2.1 Skimmer Selection Example

A skimmer is required for an offshore area with a significant amount of debris. The oil will reach a medium-to-high viscosity after 24 hours of weathering. The skimmer must have a large built-in storage capacity to ensure that it can operate for extended periods without returning to shore to discharge recovered oil. The collected oil should be relatively water-free to conserve storage space.

Step 1 From the matrix, we see that the following skimmers have a *good* rating in open water and in debris:

- Rope mop
- ZRV (zero relative velocity) rope mop
- Sorbent lifting belt

Step 2 Of these skimmers, the sorbent lifting belt is the best suited to the recovery of high viscosity oils, although rope mop and ZRV rope mop skimmers perform well in medium viscosity oils:

- Sorbent lifting belt
- Rope mop
- ZRV rope mop

Step 3 Choose a skimmer with internal storage:

- Sorbent lifting belt
- ZRV rope mop

The sorbent lifting belt skimmer would be the best choice because the oil will weather and become highly viscous.

9.3 Detailed Information on Skimmer Types

The following pages provide detailed operating information and performance characteristics of each skimmer type listed in Table 9-4.

9.3.1 Simple Weir

Operating Principle

Oil flows over a simple weir lip and is collected in a sump. Water is discharged through ports located below the weir. Some models have an onboard pump whereas others require a remote pump.

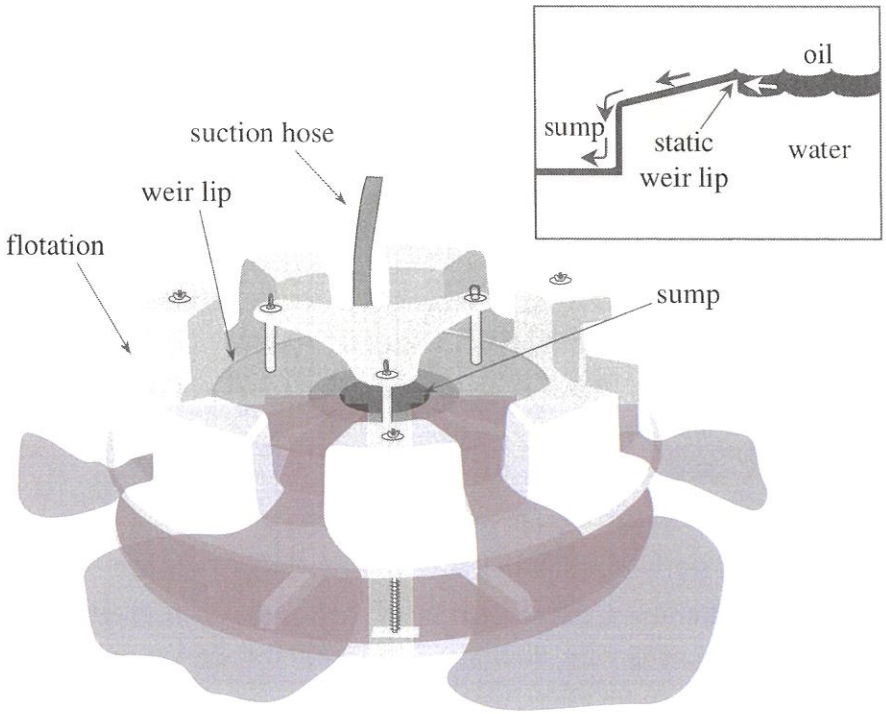

Figure 9-2 Simple Weir Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
○	○	●

Simple weir skimmers work well in thick layers of light, fresh crude oil. However, reflected waves inside containment booms combined with thin slicks can result in high water uptake. Once oil mixes with debris, weir skimmers may clog.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm	●	●

Since these skimmers recover large amounts of water, transferring with centrifugal pumps should be avoided because they will emulsify the oil. Diaphragm or peristaltic pumps are preferred when remote from the skimmer.

Advantages	Disadvantages
• Suitable for shallow water • Simple design/good reliability • Often compact • Easily deployed and operated • Lightweight	• Weir may tilt, stop running, or operate poorly if suction hose connection or skimmer touches bottom • Can be clogged by debris • Does not recover high viscosity oil • Centrifrugal pumps cause water/ oil emulsions to form (can be used with other types of pumps)

9.3.2 Self-Leveling Weir

Operating Principle

Like a simple weir, these devices skim a discrete layer toward the top of a fluid. However, self-leveling weirs use a means of adjusting the weir's height. In the examples shown below, weir height changes as the pumping rate is increased or decreased and the fluid level in the sump changes.

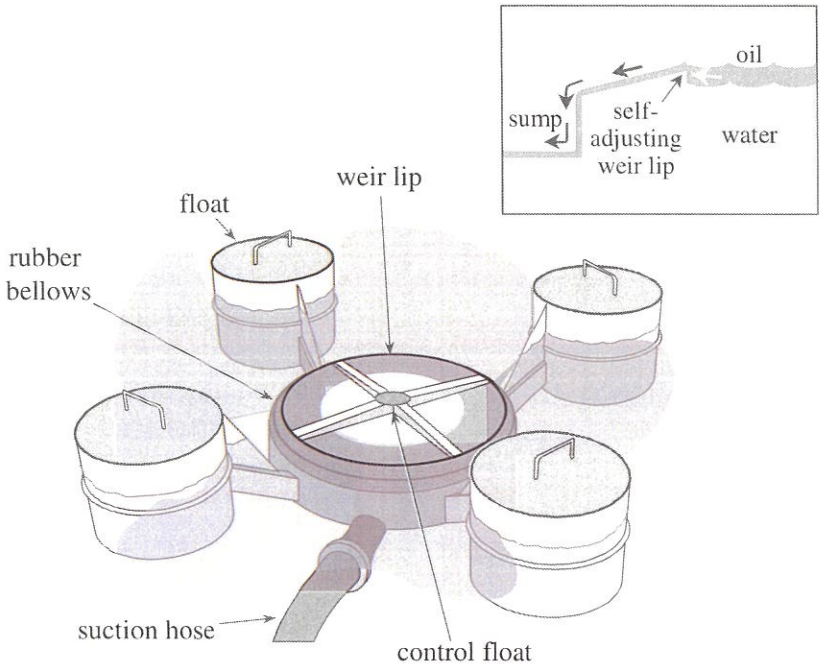

Figure 9-3 Self-Leveling Weir

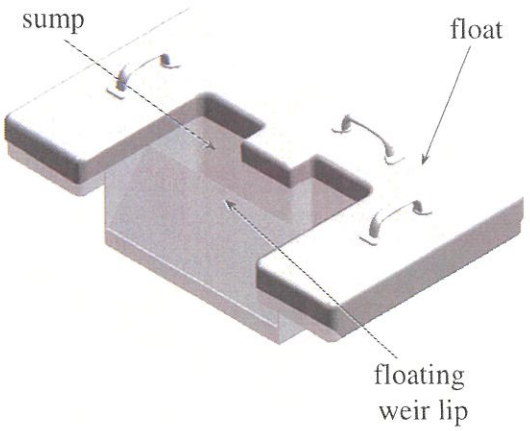

Figure 9-4 Self-Leveling Weir

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
○	○	●

Self-leveling weir skimmers are generally more effective than simple weirs. The liquid recovery rate depends on the capacity of the off-loading pump; however, they are ineffective when oil becomes too viscous to flow over the weir.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm	●	◑

The flow of oil over a self-leveling weir can be optimized by adjusting the pump speed and/or by adjusting a valve on the suction line or air or hydraulic lifters to control the weir's height. Timed measurements of the oil phase collected in a storage container can be easily made to ensure optimum flow rates. Relatively high water content in the collected liquid should be expected in thin slicks (≤ 0.15 in or several mm).

Advantages	Disadvantages
• Can operate in shallow water • Simple design/good reliability • Easily deployed and operated • Some models have debris screens	• Limited to calm water • May tilt or operate poorly if suction hose or base of skimmer touches bottom • Does not tolerate heavy oil; debris causes weir to clog • Models with centrifugal pumps emulsify recovered fluids • Rubber bellows in some models deteriorate over time

9.3.3 Weir with Integral Screw Auger

Operating Principle

A simple weir skims the top layer of fluid into a hopper directly connected to a reversible, horizontal (see inset below from Figure 9-5) or vertical (Figure 9-5) screw auger pump. Some newer models use a self-leveling weir. The screw pump drives, and is cleared by, a rotating scraper. The tightly fitted scraper seals the screw and creates a positive head at the pump discharge. Note that a number of other skimmer types, e.g., belt and brush systems, utilize a screw auger pump for transferring collected liquid and not as an integral part of the recovery mechanism.

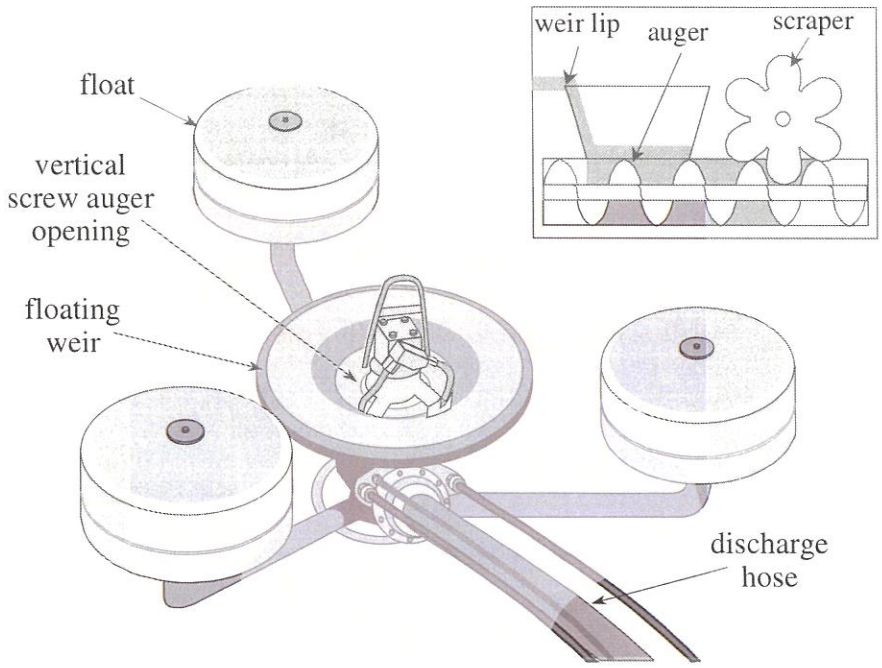

Figure 9-5 Weir with Integral Screw Auger

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
◑	○	◑

Screw auger skimmers can recover heavy, viscous oils; however, oil must flow readily for these skimmers to function well. Some heavy (viscous) oils may not flow readily over the weir. They are also suitable for processing debris.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm	○	◑

High water pickup (70–90%) should be expected and appropriate temporary storage/separation equipment must be planned for.

Advantages	Disadvantages
• Can operate in shallow water • Capable of pumping highly viscous oils mixed with debris, e.g., seaweed, ice, and wood chips • Screw auger pump neither requires priming nor forms oil/water emulsions • Easily deployed and operated	• Limited to calm and protected water with heavy, viscous oils • Performance decreases in choppy water or low viscosity oils • Heavy oils that do not flow over the weir lip must be manually pushed into the collection hopper • Can develop high back-pressure in the discharge line

9.3.4 Advancing Weir

Operating Principle

Various advancing weir skimmers are available with similar characteristics. In most devices, an initial weir lip is advanced through a slick allowing water and oil to pass into a collection/separation chamber where oil is pumped from the surface. Water is discharged through ports below. Some models, as shown in Figure 9-6, incorporate water jets to induce the flow of oil over the weir lip. Other advancing weir skimmers use impellers or eductors to draw in oil.

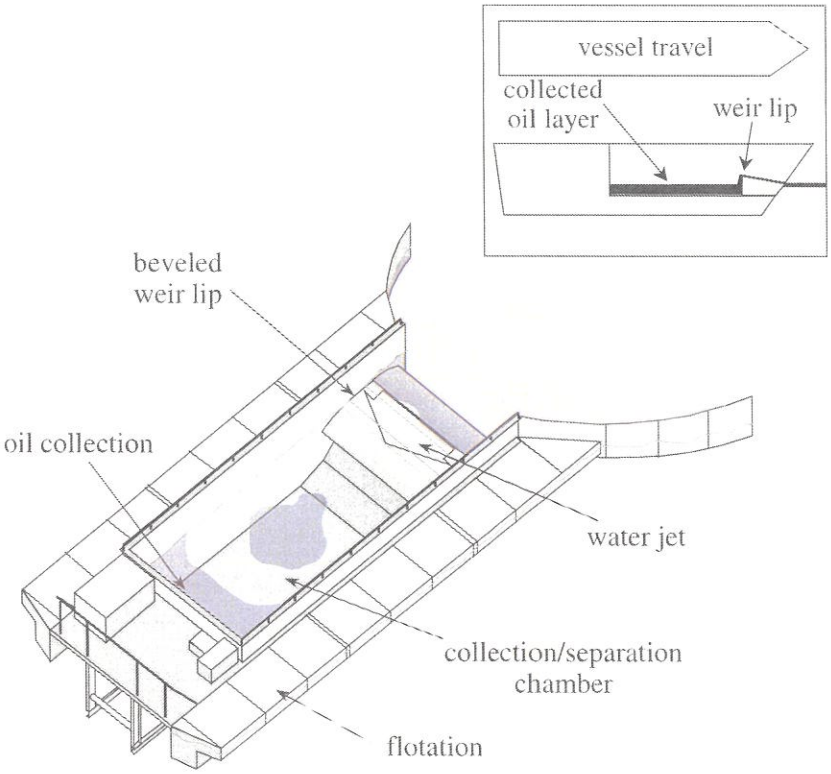

Figure 9-6 Advancing Weir Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
○	○	●

Advancing weir skimmers often use induced water flow to push oil into a containment/collection area. These units display high recovery rates in calm water and in light-to-medium viscosity oils.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Advancing	Calm/protected	◑	◑

Maximum recovery rates are achieved when a water flow angle is low, i.e., directed almost straight back (towards the stern of the vessel). Advancing weir devices that do not include induced water flow systems usually experience difficulties in maintaining the continuous flow of oil into the skimmer.

Advantages	Disadvantages
• Work well in thick layers of low and medium viscosity oil • Can tolerate some debris • Water recovery reduced by allowing water to flow through collection chamber • Operation possible in slightly rougher conditions than typical weir skimmer due to water jet/ weir design	• Not effective in higher viscosity oils • Best used in calm or protected water • Processing problems with large debris • Jet induction affected by waves and currents • Units without induced water systems may not maintain continuous oil flow

9.3.5 Weir Boom

Operating Principle

The boom is towed in a catenary shape into a slick or anchored to allow oil to be carried into it by water current and wind. Skimming weirs (horizontal slots) are built into several sections of boom at the apex. Collected oil is pumped to a vessel for storage. Various models are available including single-vessel units with boom-supported side-sweeps as well as smaller systems designed for coastal and harbor use. Although the model depicted below has a water-filled ballast chamber and inflatable flotation, weir booms with internal foam flotation and regular skirts have been produced.

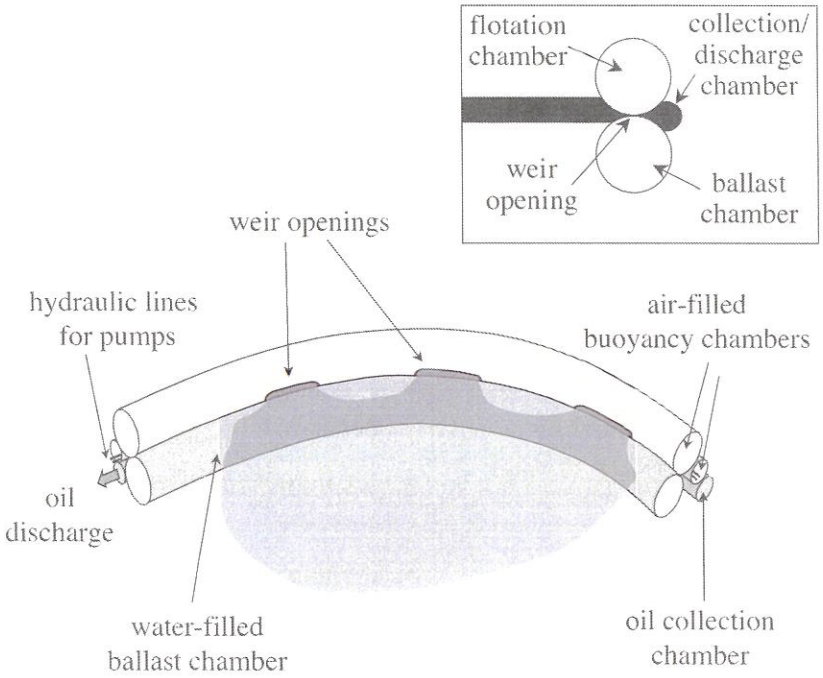

Figure 9-7 Weir Boom Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
○	○	●

Weir boom skimmers are generally capable of recovering light-to-medium viscosity oils. Although more effective in skimming thick slicks, weir booms can be used to concentrate and recover thin slicks. These skimmers generally require water depths of 4 to 5 ft (1.2 to 1.5 m) and should be towed at speeds of less than 1 kt (0.5 m/s).

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Advancing	Calm/protected	●	◑

Weir boom skimmers are often difficult to deploy, operate, and retrieve. They collect large amounts of water so that temporary storage and/or use of an oil/water separator must be planned when they are being used. When applied to spills in coastal waters, deployment problems have been experienced with weir boom skimmers. Weir booms have had low oil recovery rates in thin slicks.

Advantages	Disadvantages
• Can tolerate small debris • High pickup rate • Good wave-following ability • Some older models were designed to fit in air-deployable containers • Integral oil/water separators in some older models	• Limited to calm and protected water and thick oil slicks • Water depth of 4–5 ft (1.2–1.5 m) required • Generally exhibit low collection efficiency • Can be difficult to deploy and retrieve • Mechanically complex • Pumps that emulsify oil included in some models • Weir opening can be difficult to maintain at the optimum level • Collect large amounts of water

9.3.6 Drum

Operating Principle

One or more oleophilic drums that are driven by hydraulic, pneumatic, or electric motors are rotated downward into an oil slick. Recovered oil is then scraped off the drum(s) into a trough and, in some models, a sump. Either external or onboard discharge pumps are available. Some newer skimmers feature a mechanism to allow an operator to adjust the drum submersion depth.

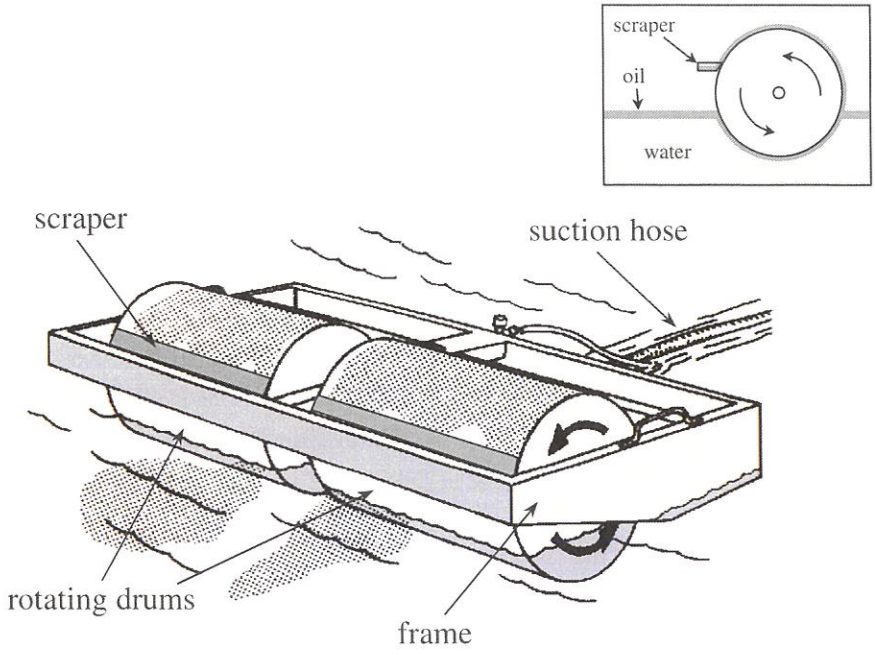

Figure 9-8 Drum Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
◑	○	◑

Rotational speeds of approximately 40 rpm (revolutions per minute) result in the maximum recovery rate of medium viscosity oils. Reducing the rotational speed to 20 rpm generally improves the oil content in the recovered liquid by 10% but lowers the recovery rate by 50%.

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm/protected	◑	○

Waves often significantly decrease the recovery rate of self-contained (i.e., not vessel-mounted) drum skimmers. Calm water operation is recommended.

Advantages	Disadvantages
• Small units can be operated in shallow water • Simple design/good reliability • Often compact (including onboard pump) • Many models can be lifted by 2 people • High oil/water pickup ratio • Can tolerate some debris • Can be used in calm, harbor, and some offshore applications	• Limited to calm and protected water • Will not recover solidified/highly viscous oils due to pumping/oil flow problems • Will not recover dispersant-treated oil • Reduced recovery rate in thin slicks can occur if the drum water-wets • Limited capacity sump

9.3.7 Grooved Drum or Disc

Operating Principle

One or more oleophilic drums that are driven by hydraulic, pneumatic, or electric motors are rotated downward into an oil slick. The grooved disc skimmer replaces the flat discs (Section 9.3.8) with discs with shallow grooves and corresponding scrappers. A key difference is that this skimmer has a series of triangular-shaped groves on the drums or discs (Figure 9-9). This pattern maximizes the surface area of the drum and allows menisci to be formed in the depth of each channel which increases the amount of recovered oil. Recovered oil is then scraped off into a trough and, in some models, into a sump. Either external or onboard discharge pumps are available.

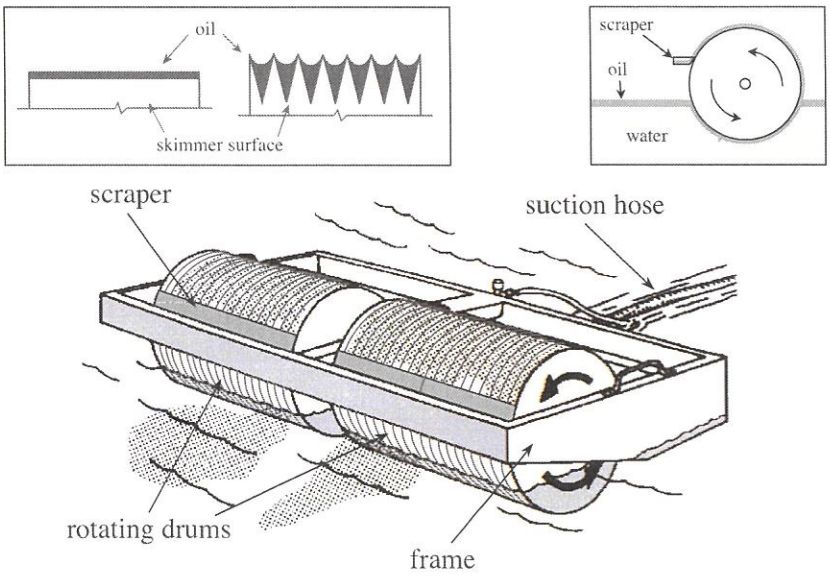

Figure 9-9 Grooved Drum Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
○	○	◑

Rotational speeds of approximately 65 rpm result in the maximum recovery rate of medium viscosity oils.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm/protected, limited offshore	◑	○

Waves often significantly decrease the recovery rate of self-contained (i.e., not vessel-mounted) grooved drum skimmers. Calm water operation is recommended.

Advantages	Disadvantages
• Very high oil/water pickup ratio • Small units can be operated in shallow water • Simple design/good reliability • Often compact (including onboard pump) • Many models can be lifted by 2 people • Can tolerate some debris • Can be used in calm, harbor, and some offshore applications	• Limited to calm and protected water • Will not recover solidified/highly viscous oils due to pumping/oil flow problems • Will not recover dispersant-treated oil • Limited capacity sump

9.3.8 Disc

Operating Principle

A series of oleophilic discs are arranged in a linear (i.e., single row), triangular (3 banks of discs), circular ("toroidal"), or square (4 banks of discs) configuration. Each group of discs is rotated downward into the oil, driven by hydraulic, pneumatic, or electric motors. PVC or aluminum scrapers remove oil adhering to the discs, and it flows down tubes or directly into a sump. Some smaller skimmers have external discharge pumps while other models have onboard pumps.

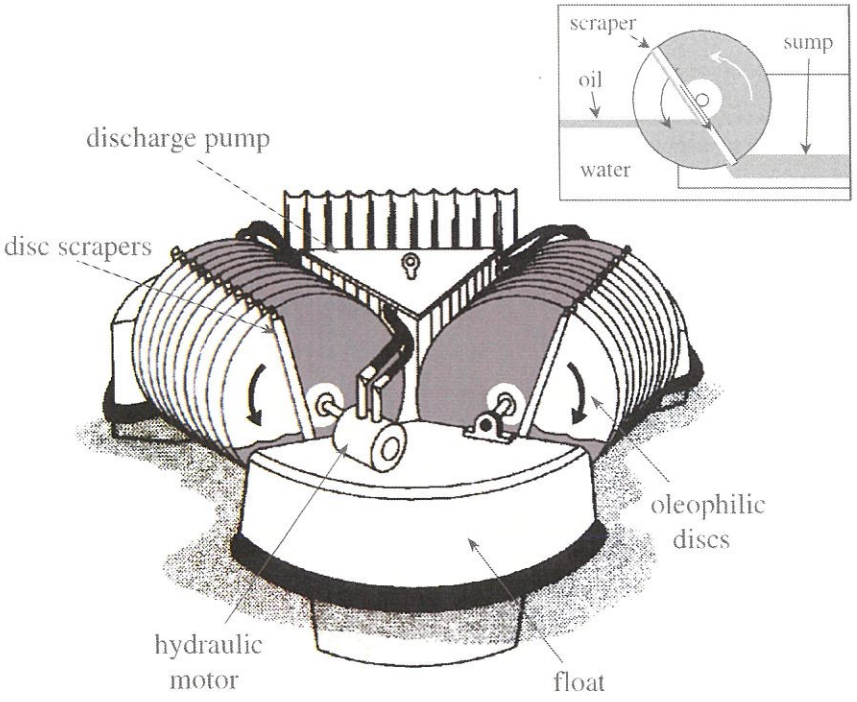

Figure 9-10 Disc Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
◑	○	●

Disc skimmers recover liquid containing a high percentage of oil but can clog with debris. Down-tubes, scrapers, and discs should be cleaned frequently even when operating in what appears to be debris-free water.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm	●	○

A disc speed of approximately 40 rpm optimizes oil recovery rate in most oils. Light oils, e.g., diesel, may require a lower rpm to reduce water uptake. Skimmer operation is optimal in calm and low wave conditions, but deteriorates if there is splash against the discs or skimmer body.

Advantages	Disadvantages
• Small units can be operated in shallow water • Few moving parts/good reliability • Often compact • Models with onboard pump function well • Smaller units can be lifted by 2–3 people • High oil/water pickup ratio • Oil can be recovered from all directions by models with 3, 4, and circular banks of discs • Can be used in calm, protected, and some offshore applications	• Not effective in heavy chop • Scrapers can be clogged by debris • Will not recover solidified/highly viscous oil • Will not recover dispersant-treated oil • Down-tubes may be clogged by heavy oil

9.3.9 Fabric-Coated Disc or Drum

Operating Principle

A series of fabric-coated oleophilic discs are arranged in a single row or in sets. The discs rotate downward into the oil, driven by hydraulic, pneumatic, or electric motors. PVC or aluminum scrapers remove oil adhering to the discs and it flows down tubes or directly into a sump. Some smaller skimmers have external discharge pumps while other models have onboard pumps. These pumps are essential to remove the high quantity of oil collected into the sump by the fabric coated discs. A similar system using drums has been developed as well.

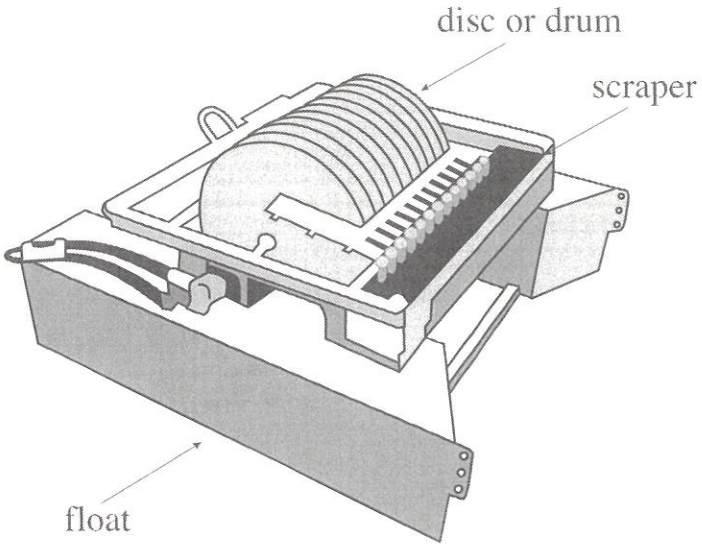

Figure 9-11 Fabric-Coated Disc Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
◑	○	◑

Disc skimmers recover liquid containing a high percentage of oil but can clog with debris. Tubes, scrapers, and discs should be cleaned frequently even when operating in what appears to be debris-free water.

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	Calm, some offshore applications	●	○

A disc speed of approximately 40 rpm optimizes oil recovery rate in most oils. Light oils, e.g., diesel, may require a lower rpm to reduce water uptake. Skimmer operation is optimal in calm and low wave conditions, but deteriorates if there is splash against the discs or skimmer body.

Advantages	Disadvantages
• Very high oil/water pickup ratio • Small units can be operated in shallow water • Few moving parts/good reliability • Models with onboard pump function well • Smaller units can be lifted by 2-3 people • Can be used in calm, protected, and some offshore applications	• Not effective in heavy chop • Scrapers can be clogged by debris • Will not recover solidified/highly viscous oil • Will not recover dispersant-treated oil • Tubes may be clogged by heavy oil

9.3.10 Rope Mop

Operating Principle

Single or multiple polyethylene fiber ropes are pulled through a slick by wringer-rollers. The rope mop is wrung and then continuously returned to the slick, repeating the cycle. Recovered oil is collected below the wringer assembly or pumped via a suction hose. Some models require a return pulley while those operated vertically are simply suspended above the slick so that the rope mop contacts the oil.

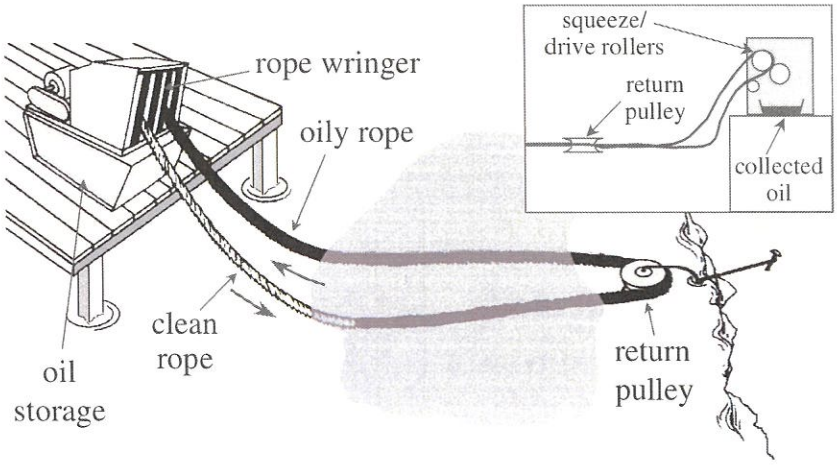

Figure 9-12 Horizontal Rope Mop Skimmer

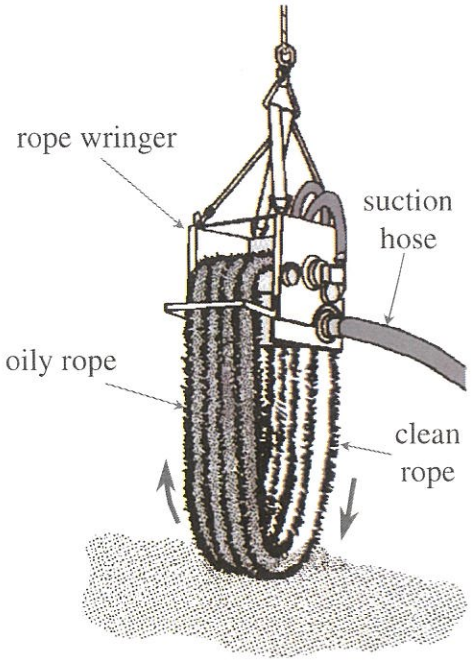

Figure 9-13 Vertical Rope Mop Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
◑	○	●

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary	All	○	○

Rope mop skimmers generally function best in warm weather (>68°F or >20°C) in medium viscosity oils that adhere to the mop. Operation in colder weather and lighter oils is possible, although the rope mop can freeze in low temperatures if it recovers water. The oil content in the collected liquid declines as mop speed exceeds about 1.25 ft/s (0.4 m/s).

Recovery in low waves of 1–2 ft (30–60 cm) should be possible. If oil is emulsified and viscous, rope mop strands can mat together and jam the wringer assembly. Low pickup rates of light oils, e.g., diesel, are common.

Advantages	Disadvantages
• Effective in calm, protected, and open water • Can operate in any water depth (and over dry patches) • Good pickup rate for medium viscosity oils • Wide, effective reach • Can tolerate most debris • Rope can recover oil in low currents • Can operate in broken ice	• Ropes and wringer-rollers will wear if oil is mixed with sand • Inefficient unless oil is confined or pooled • Attachment points/lines required for tail (return) pulley (horizontal models only) • Tail pulley may have to be repositioned when tide changes • Not effective in highly viscous oil

9.3.11 Zero Relative Velocity (ZRV) Rope Mop

Operating Principle

The standard configuration of a ZRV rope mop skimmer consists of a series of oleophilic ropes mounted and pulled in between the hulls of a self-propelled catamaran vessel. The rope mops are operated so that they contact the oil/water surface at the same speed as the vessel encounters slicks, resulting in zero relative velocity between the rope mops and the oil. Therefore, ZRV rope mop skimmers are effective in high currents. Hydraulically-driven squeeze rollers wring out the oil-laden rope mops. These skimmers must be advanced through slicks. They do not function well in the stationary mode. Recovered oil is stored onboard the vessel until it can be off-loaded.

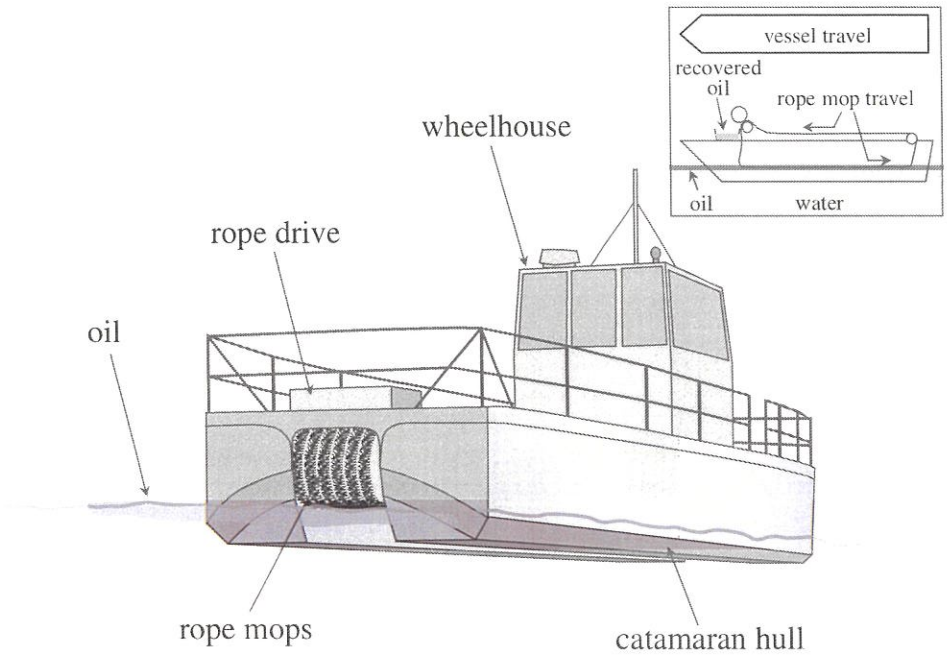

Figure 9-14 ZRV Rope Mop Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
◑	○	●

ZRV rope mop skimmers function best in warm weather (>68°F or >20°C) in medium viscosity oil that adheres to the mop. Operation in colder weather and lighter oils is possible; however, the rope mops freeze at temperatures of 32°F (0°C) and below.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Advancing	Open	○	○

Oil recovery in low waves of 1–2 ft (30–60 cm) should be possible. Rope mop strands can mat together and jam wringer assemblies in emulsified and/or viscous oil (Bunker C, weathered crude). Low pickup rates of light oils, e.g., diesel, should be expected.

ZRV skimmers can be operated in speeds up to 3 knots (5.5 km/hr).

Advantages	Disadvantages
• Effective in calm and protected water • Good oil recovery in oil slicks thicker than ¼ in (6 mm), e.g., in embayments or near ice edges • Good oil/water pickup ratio • Onboard oil storage • Generally, good working conditions for crew	• Water depths greater than 3 ft (1 m) are required by most models • Difficult to transport to remote areas • A portion of some oils may flow by the rope mops and be left behind

9.3.12 Sorbent Lifting Belt

Operating Principle

An inclined oleophilic belt is advanced through a slick so that oil and debris are conveyed up the belt. Collected debris is scraped off and oil adhering to the belt is squeezed from it. In some models, an induction pump is positioned behind a semi-porous belt located just below the waterline. The pump impeller draws liquid through the belt, forcing oil onto and into the belt.

Sorbent and non-sorbent belt skimmers have been designed that rely on a belt that moves down into the water. The downward moving belt is described in Section 9.3.13 and is referred to as the submersion plane/belt skimmer.

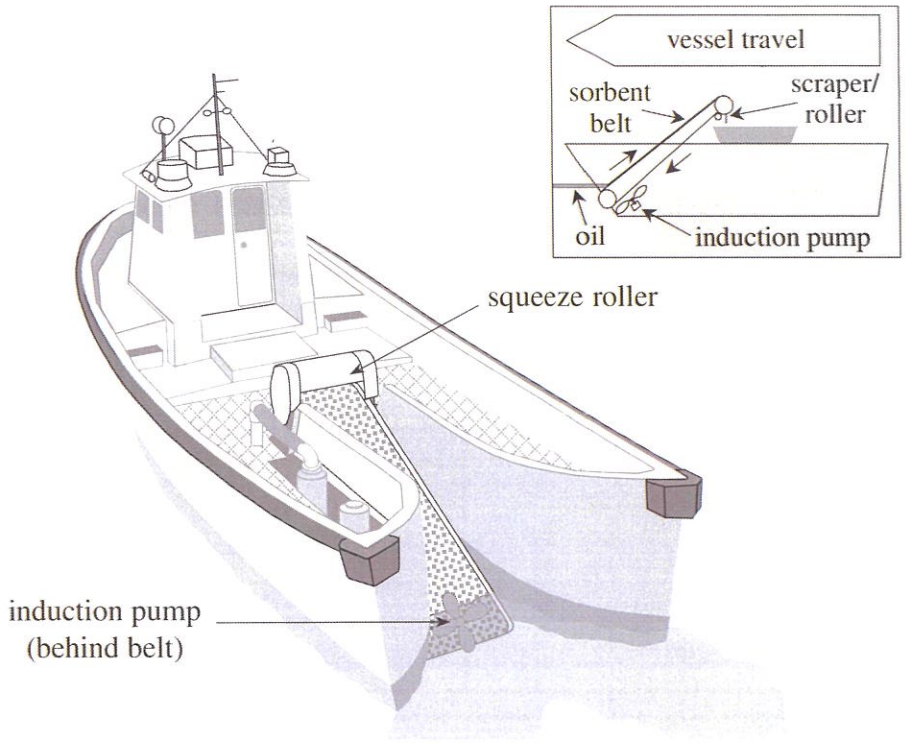

Figure 9-15 Sorbent Lifting Belt

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
●	○	○

Sorbent belt skimmers display good recovery rates for both fresh and viscous, debris-laden oil. They can recover light sheens but the percent oil recovered is low.

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Stationary/ Advancing	All	○	◑

Self-propelled barges outfitted with belt skimmers can be effective in nearshore recovery operations due to their mobility, high recovery rate and storage capacity. The percent oil recovered is low with some types of belt skimmers but heated tanks in some models allow recovered water to be readily separated from oil and decanted.

Advantages	Disadvantages
• Effective in calm, protected, and open water • Some types allow debris collection • High oil recovery rate • Larger, self-propelled models have onboard storage • Self-propelled models can be deployed to remote sites • Recover highly viscous oils • Effective in a wider range of oils than many other skimmers • Can be disassembled for transport	• Larger units cannot operate in shallow water • Operation by qualified seamen required for larger models • Some models are mechanically complicated and difficult to maintain • Assembly of some models requires skilled mechanic and lifting gear • Belt life for some models can be relatively short • A portion of some oils may flow through the belt and surface behind these skimmers

9.3.13 Brush

Operating Principle

Closely spaced brushes collect oil, which is then removed by a comb-like scraper before being conveyed to storage. On some smaller models, brushes are mounted on a drum. Most larger models employ multiple linear chains deployed from the side (as shown below) or bow of a dedicated vessel or a vessel of opportunity. Side collectors require a jib, boom, multiple cables, and onboard storage and are often positioned on existing vessels used for multiple purposes, including spill response and fire fighting.

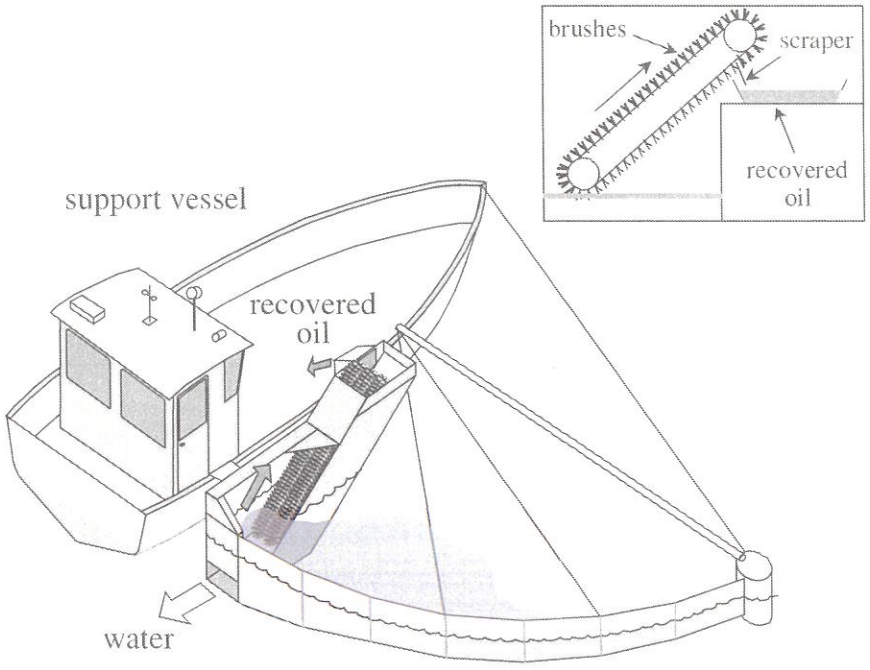

Figure 9-16 Brush Skimmer

Expected Performance		
Low viscosity oil	**Medium viscosity oil**	**High viscosity oil**
●	○	○

Operational Considerations

Mode	Sea State	Debris Tolerance	% Oil Recovery
Advancing	Open	○	◑

Brush skimmers function optimally in medium and high viscosity oils, provided that a suitable pump is used to transfer the latter to storage. Highest oil recovery rates in viscous products occur when brush drums are operated at approximately 20 rpm. However, the percent oil recovered in the collected liquid is highest at 5 to 10 rpm. The higher oil content is achieved at the expense of oil recovery rate, which decreases in direct relation to the decrease in rpm.
